# Appendix D

## Risk Estimates

# Adopted Toxicity Data - Inhalation Pathway

**Adopted Toxicity Data**

| Individual Compounds | Inhalation Unit Risk (IUR) (a) ($\mu g/m^3)^{-1}$ | Source | Reference Concentration (RfC) ($\mu g/m^3$) | Source | Background Exposure Allocation (%) | Source |
|---|---|---|---|---|---|---|
| antimony | - | - | 21 | RIVM (2008). Converted from TDI of 0.006 mg/kg/day. | 0% | Negligible. |
| arsenic | - | - | 1 | RIVM (2000). | 0% | ASC NEPM (2013). |
| cadmium | - | - | 0.005 | WHO (2000a). | 20% | ASC NEPM (2013). |
| chromium III | - | - | 0.1 | ATSDR (2008) | 0% | ASC NEPM (2013). Consistent with CrVI. |
| chromium VI | - | - | 0.1 | US EPA IRIS (2015). | 0% | ASC NEPM (2013). |
| lead | - | - | 0.5 | WHO (2000a). | 0% | Negligible. |
| manganese | - | - | 0.15 | WHO (2000b). | 20% | ASC NEPM (2013). |
| mercury | - | - | 0.2 | WHO (2003). | 10% | ASC NEPM (2013). |
| nickel | - | - | 0.02 | EA (2009). | 20% | ASC NEPM (2013). |
| cyanide | - | | 0.8 | USEPA (2010). | 0% | ASC NEPM (2013). |
| Dioxins and furans (PCDDs and PCDFs) | - | - | 0.00000805 | DEH (2005). Converted NHMRC TMI (70 pg/kg body weight/month) to TDI ($2.3 \times 10^{-9}$ mg/kg/day) to RfC. | 57% | DEH (2004) |
| PAHs as benzo(a)pyrene* | 8.70E-02 | WHO (2000b). TEF (1) | - | - | - | - |
| toluene | - | - | 5000 | US EPA IRIS (2015). | 0% | Friebel & Nadebaum (2011). |
| acetone (propanone) | - | - | 30900 | ATSDR (1994). Converted from chronic MRL of 13 ppm. | 10% | Friebel & Nadebaum (2011) (b) |
| benzene | 6.00E-06 | WHO (2010). | 30 | US EPA IRIS (2015). | 20% | Friebel & Nadebaum (2011). |
| Naphthalene* | - | - | 3.7 | ATSDR (2005) | 0% | Negligible. ATSDR (2005). |

**Notes**
CSF - Cancer slope factor.
RfD - Reference dose.
TDI - Tolerable daily intake.
TMI - Tolerable monthly intake.
(a) Those compounds with inhalation unit risk (IUR) values were considered to be carcinogens as part of this assessment. It should be noted that some compounds were assessed as both a carcinogen and non-carcinogen e.g. benzene.
(b) In absence of compound-specific background exposure data, the background exposure for semi or volatile CoPC has been set at 10% in accordance with the total petroleum hydrocarbon (TPH) background exposure allocation adopted by CRC CARE (2011) during derivation of the Health Screening Levels (HSLs).

# Risk Estimate for Resident - Inhalation Pathway (Scenario 1)

**Health Risk Calculations - Inhalation of Vapour**
**Site** Regain Tomago Facility
**Address** 638 Tomago Road, Tomago
**Client** Regain Services Pty Ltd
**Scenario:** Inhalation of Vapour by Off-site Residents (Adult and Child)

$$Exposure\ Adjusted\ Air\ Concentration\left(\frac{\mu g}{m^3}\right) = \frac{Cair\ \left(\frac{\mu g}{m^3}\right) \times ET\ \left(\frac{h}{d}\right) \times EF\ \left(\frac{d}{y}\right) \times ED(y)}{AT(h)}$$

| Parameter | Description and Units | Adopted Value | | Notes |
|---|---|---|---|---|
| | | Adult | Child | |
| Cair | Chemical concentration in air (µg/m$^3$) | See model below | | Grid maximum ground level concentration (GLC) |
| ET | Exposure time (hours/day) | 24 | 24 | ASC NEPM (2013) - low to medium density residential |
| EF | Exposure frequency (days/year) | 365 | 365 | ASC NEPM (2013) - low to medium density residential |
| ED | Exposure duration (years) | 29 | 6 | ASC NEPM (2013) - low to medium density residential |
| AT | Averaging time - Non-threshold (hours) | 613200 | 613200 | ASC NEPM (2013) - low to medium density residential |
| | Averaging time -Threshold (hours) | 254040 | 52560 | ASC NEPM (2013) - low to medium density residential |

| CoPC | Maximum Annual Average GLC (µg/m$^3$) | Reference Concentration (RfC) (µg/m$^3$) | Background Concentration (%) | Background Adjusted Reference Concentration (µg/m$^3$) | Inhalation Unit Risk (µg/m$^3$)$^{-1}$ | Adult | | | | Child | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

**Potential Concentration in Soils Following Dust Deposition (Scenario 1)**

**Site** Regain Tomago Facility
**Address** 638 Tomago Road, Tomago
**Client** Regain Services Pty Ltd

***Concentration in Soils***

$$C_s = \frac{DR \times (1 - e^{-k \times t})}{d \times \rho \times k} \times 1000$$

| Parameter | Description and Units | Adopted Value | | Notes |
|---|---|---|---|---|
| $C_s$ | Concentration of CoPC in soil (mg/kg) | See below | | Calculated using above equation (Stevens, 1991). |
| DR | Particle deposition rate for accidental release (mg/m$^2$/year) | See below | | Maximum modelled deposition rate for receptors combined. |
| k | Chemical-specific soil-loss constant (1/year) = ln(2)/$T^{0.5}$ | See below | | Calculated using equation ln(2)/$T^{0.5}$. |
| $T^{0.5}$ | Chemical half-life in soil (years) | See below | | Howard et al. (1991) for PAHs (benzo(a)pyrene) and hexachlorobenzene. NHMRC (2002) for dioxins and furans (surface soil). Conservative value adopted for heavy metals in the absense of published data. |
| t | Accumulation time (years) | 25 | | Emissions may occur for the assumed lifetime of the Facility. |
| d | Soil mixing depth (m) | 0.01 | 0.15 | It is assumed that the soil where deposition occurs is not well mixed (as would be the case in a garden or cultivated bed), and hence the mixing depth for depositied soils and dusts has been taken to be 1cm. For the assessment of potential plant uptake, a soil mixing zone of 15cm has been assumed within the root zone of plants. |
| ρ | Soil bulk-density (g/m$^3$) | 1.60E+06 | | Sandy soils (representative of surface soils) typically have bulk densities between 1.3 g/cm$^3$ to 1.7 g/cm$^3$ (McKenzie et al., 2004). In general, bulk densities greater than 1.6 g/cm$^3$ tend to restrict root growth. |
| 1000 | Conversion from g to kg | - | | |

| CoPC | Deposition Rate (total) (mg/m$^2$/year) | k (1/year) | $T^{0.5}$ (years) | $C_s$ (mg/kg) - Surface Soil | $C_s$ (mg/kg) - Soil-Plant Root Zone |
|---|---|---|---|---|---|
| antimony | | Not bioaccumulative (WHO, 2003) | | | |

WHO, 2003. Antimony in Drinking Water. Background Document for Development of WHO Guidelines for Drinking Water Quality

For metals that were considered to be bioaccumulative and/or persistent, a conservative half-life value of 100 years was adopted in the absence of published data to account for the slow (or no) breakdown in the environment.

* Based on the Total PAH stack testing results collated from 2014 to 2016, the carcinogenic PAHs (Benzo(a)anthracene, Benzo(b+j)fluoranthene, Benzo(k)fluoranthene, Benzo(g,h,i)perylene, Chrysene, Dibenz(a,h)anthracene, and Indeno(1,2,3-c,d)pyrene) have been assessed as BaP, and the average percent contribution of the carcinogenic PAHs to the Total PAH is 0.67%. The remaining contribution of PAHs (99.3%) has been assessed as naphthalene. The speciated breakdowns of the Total PAH stack testing results are presented in Appendix G.

| **Client** | Regain Services Pty Ltd |
| **Scenario:** | Ingestion of Homegrown Produce by Off-site Residents (Adult and Child) |

***Concentration in Home-grown Produce***

*Deposited Material on Aboveground Plants*

$$C_p = \frac{DR \times F \times (1-e^{-k \times t})}{Y \times k}$$

| Parameter | Description and Units | Adopted Value | Notes |
|---|---|---|---|
| $C_p$ | Concentration of CoPC in plant (mg/kg plant - wet weight) | See below | Calculated using above equation from HHRAP (Stevens, 1991). |
| DR | Particle deposition rate for accidental release (mg/m$^2$/day) | See below | Maximum modelled deposition rate for receptors combined. |
| F | Fraction for the surface area of plant (unitless) | 0.051 | For leafy aboveground crops, the surface area fraction (or plant interception fraction - how much of the depositing material remains on the plant) is estimated to be 0.051 (Stevens, 1991). |
| k | Chemical-specific loss constant for particles on plants (1/days) = ln(2)/T$^{0.5}$ | See below | Calculated using equation ln(2)/T$^{0.5}$. |
| T$^{0.5}$ | Chemical half-life on plant (days) | 14 | Weathering of particulates on plant surfaces does occur and in the absence of measured data, it is generally assumed that organics deposited onto the outer portion of plant surfaces have a weathering half-life of 14 days (Stevens, 1991). Conservative value adopted for heavy metals in the absense of published data. |
| t | Deposition time or length of growing season (days) | 70 | The growing season for typical aboveground plants varies, however it may be up to 70 days (i.e. tomatoes), which has been used in the calculation on concentrations during normal operations. |
| Y | Crop yield (kg/m$^2$) | 2 | Given that the residential areas surrounding the Site are typically urban low-density residential properties, the types of edible plant expected to be grown on the properties include tomatoes and beans. Corn, hay and wheat are not expected to be grown for human consumption in significant quantities in the area. For typical crops grown aboveground an average crop yield of 2 kg/m$^2$ has been adopted. |

| CoPC | DR (mg/m$^2$/day) | k (1/days) | $C_p$ (mg/kg plant - wet weight) |

*Uptake of Chemicals via Roots*

$$C_{rp} = C_s \times RUF$$

| Parameter | Description and Units | Adopted Value | Notes |
|---|---|---|---|
| $C_{rp}$ | Concentration of persistent CoPC in root of plant (mg/kg plant - wet weight) | See below | Calculated using above equation (US EPA, 2005). |
| $C_s$ | Concentration of persistent CoPC in soil assuming 15 cm mixing depth within gardens (mg/kg) | See below | Refer to Dust Deposition Model. |
| RUF | Root uptake factor (unitless) | See below | RAIS (Accessed 2018). Soil to wet plant uptake factor adopted. Value for 2,3,7,8-TCDD conservatively selected for dioxins and furans. |

| CoPC | Cs (mg/kg) - Soil-Plant Root Zone | RUF (unitless) | $C_{rp}$ (mg/kg plant - wet weight) |
|---|---|---|---|
| arsenic | 2.92E-13 | 1.00E-02 | 2.92E-15 |
| cadmium | 4.56E-12 | 1.38E-01 | 6.30E-13 |
| chromium | 2.84E-12 | 1.87E-03 | 5.31E-15 |
| lead | 1.63E-12 | 1.12E-02 | 1.82E-14 |

**Health Risk Calculations - Ingestion of Poultry and Eggs (Scenario 1)**
**Site** Regain Tomago Facility
**Address** 638 Tomago Road, Tomago
**Client** Regain Services Pty Ltd
**Scenario:** Ingestion of Poultry and Eggs by Off-site Residents (Adult and Child)

***Concentration in Eggs***

$$A_{egg} = [\Sigma(F_i \times Qpi \times Pi) + Qs \times Cs \times Bs] \times (Ba_{egg})$$

| Parameter | Description and Units | Adopted Value | Notes |
|---|---|---|---|
| $A_{egg}$ | Concentration of COPC in eggs (mg COPC/kg FW tissue) | See model below | Calculated using above equation. |
| $F_i$ | Fraction of plant type (i) (grain) grown on contaminated soil and ingested by the animal (chicken) (unitless) | 1 | Recommended by HHRAP (US EPA, 2005). Assumed 100% of the plant material eaten by chickens were grown on soil contaminated by emission sources. |
| $Qp_i$ | Quantity of plant type (i) (grain) eaten by the animal (chicken) each day (kg DW plant/day) | 0.2 | Recommended by HHRAP (US EPA, 2005). Estimated for grain feed only. |
| $P_i$ | Concentration of CoPC in plant type (i) (grain) eaten by the animal (chicken) (mg/kg DW) | See home-grown produce model | Refer to $C_p$ and $C_{rp}$ (mg/kg plant - wet weight). Although $C_p$ and $C_{rp}$ are presented as a wet weight, this is unlikely to affected the outcome of the assessment as dust deposition rates included both wet and dry deposition. |
| Qs | Quantity of soil eaten by the animal (chicken) (kg/day) | 0.022 | Recommended by HHRAP (US EPA, 2005). |
| Cs | Average soil concentration over exposure duration (mg CoPC/kg soil) | See dust-deposition model | Refer to $C_s$ Soil-Plant Root Zone (mg/kg) |
| Bs | Soil bioavailability factor (unitless) | 1 | Default value recommended by HHRAP (US EPA, 2005). |
| $Ba_{egg}$ | CoPC biotransfer factor for eggs (day/kg FW tissue) | See model below | The highest biotransfer factor for eggs recommended by the HHRAP Database (US EPA, 2005) or published by OEHHA (2015) was conservatively selected in the HHRA.<br>OEHHA values were adopted for arsenic, lead, mercury, nickel and dioxins and furans (value for 2,3,7,8-TCDD adopted for dioxins and furans).<br>HHRAP Database values were adopted for chromium and PAHs. For chromium, an egg biotransfer coefficient was not available and therefore fat transfer coefficients were estimated from the beef transfer coefficient. The egg biotransfer coefficient was then estimated by using the fat transfer coefficient and assumed that eggs contain a fat content of 8% consistent with US EPA (2005) and the following equations:<br>$Ba_{beef} = 10^{logBafat} \times 0.19$<br>$Ba_{egg} = 10^{logBafat} \times 0.08$ |

| CoPC | Concentration of CoPC in Plant (mg/kg DW) ($P_i$) | Cs (mg/kg) - Soil-Plant Root Zone | $A_{egg}$ | |
|---|---|---|---|---|
| | | | CoPC biotransfer factor for eggs ($Ba_{egg}$) (day/kg FW tissue) | Concentration of COPC in eggs ($A_{egg}$) (mg COPC/kg FW tissue) |
| arsenic | 1.52E-12 | 2.92E-13 | 7.00E-02 | 2.18E-14 |
| cadmium | 2.44E-11 | 4.56E-12 | 1.00E-02 | 4.99E-14 |
| chromium | 1.48E-11 | 2.84E-12 | 2.32E-03 | 7.01E-15 |
| lead | 8.50E-12 | 1.63E-12 | 4.00E-02 | 6.94E-14 |
| mercury | 1.47E-12 | 2.70E-13 | 8.00E-01 | 2.40E-13 |
| nickel | 3.21E-11 | 6.14E-12 | 2.00E-02 | 1.31E-13 |
| dioxins and furans as PCDD and PCDF | 3.06E-17 | 3.79E-18 | 1.00E+01 | 6.21E-17 |
| PAHs as benzo(a)pyrene* | 5.45E-12 | 9.52E-14 | 1.58E+00 | 1.73E-12 |

***Ingestion of Eggs***

$$Intake\ Factor = \frac{IR \times FI \times ME \times EF \times ED}{BW \times AT}$$

$$Daily\ Intake = Aegg \times Intake\ Factor$$

| Parameter | Description and Units | Adopted Value | | Notes |

**Health Risk Calculations - Ingestion of Breastmilk (Scenario 1)**

**Site** Regain Tomago Facility
**Address** 638 Tomago Road, Tomago
**Client** Regain Services Pty Ltd
**Scenario:** Ingestion of Breastmilk by Off-site Residents (Child)

***Concentration in Breastmilk***

$$C_{milk\ fat} = \frac{m \times h \times f_1}{0.693 \times f_2}$$

| Parameter | Description and Units | Adopted Value | Notes |
|---|---|---|---|
| $C_{milk\ fat}$ | Concentration of CoPC in milk fat (mg/kg) | See model below | - |
| m | Average maternal intake (mg/kg/day) | See model below | The potential maternal intake is a highly variable parameter in the above equation. It can be assumed that the calculations undertaken to calculate adult intake of each CoPC via inhalation and ingestion are relevant for a mother who may be breastfeeding an infant. |
| h | Half-life of chemical in body, adults (days) | See model below | Value from NHMRC (2002) for dioxins and furans. Value from HSDB online database for PAHs (current to 2010). Value from WHO (2011), NHMRC (2016) or the HSDB online database for most metals. For mercury, the biological half-life is stated to be 'many years', which was assumed to be 10 years. |
| $f_1$ | Fraction of ingested chemical stored in fat (unitless) | 0.9 | No data is available that is specific to the fraction of organic chemicals that may be stored as fat and hence available data for dioxins has been adopted. The fraction of ingested organic chemicals which is stored as fat is recommended to be 0.9 (US EPA, 1998). |
| $f_2$ | Fraction of mothers weight that is fat (unitless) | 0.35 | The recommended fraction of mother's body weight which is fat is 0.35 (for females in south-eastern urban areas of Australia aged 31 to 45 years (DEH, 2005)). |

| CoPC | Adult intake from air, soil (ingestion and dermal contact), home-grown, produce, eggs and beef (m) (mg/kg/day) | Half-life of chemical in body, adults (h) (days) | Concentration of CoPC in milk fat ($C_{milk\ fat}$) (mg/kg) |
|---|---|---|---|
| arsenic | 4.05E-10 | 60 | 9.01E-08 |
| cadmium | 6.52E-09 | 5475 | 1.33E-04 |
| chromium | 4.04E-09 | 83.4 | 1.25E-06 |
| lead | 2.31E-09 | 10950 | 9.39E-05 |
| mercury | 3.84E-10 | 3650 | 5.20E-06 |
| nickel | 8.78E-09 | 1.8 | 5.86E-08 |
| dioxins and furans as PCDD and PCDF | 8.36E-15 | 2555 | 7.93E-11 |
| PAHs as benzo(a)pyrene* | 6.17E-10 | 5.5 | 1.26E-08 |

***Daily Intake from Air***

$$Intake\ Factor = \frac{InhR \times ET \times FI \times EF \times ED}{BW \times AT}$$

| Parameter | Description and Units | Adopted Value (Adult) | Notes |
|---|---|---|---|
| Intake Factor | Intake factor ($m^3$/kg/day) | See model below | - |
| InhR | Inhalation Rate ($m^3$/hour) | 1.34 | Inhalation rate assuming 20 hours indoors at 1.17 $m^3$/hour and 4 hours outdoors at 2.2 $m^3$/hour. |
| ET | Exposure time (hours/day) | 24 | ASC NEPM (2013) - low to medium density residential. |
| FI | Fraction inhaled from contamination source (unitless) | 1 | Assumed intake from contamination source for the whole ET. |
| EF | Exposure frequency (days/year) | 365 | ASC NEPM (2013) - low to medium density residential |
| ED | Exposure duration (years) | 29 | ASC NEPM (2013) - low to medium density residential |
| BW | Body weight (kg) | 70 | ASC NEPM (2013) - low to medium density residential |
| AT | Averaging time - Non-threshold (days) | 25550 | ASC NEPM (2013) - low to medium density residential |
| | Averaging time -Threshold (days) | 10585 | ASC NEPM (2013) - low to medium density residential |

| CoPC | Grid Maximum GLC (mg/$m^3$) | Non-Threshold Slope Factor (mg/kg/day)$^{-1}$ (a) | Background Adjusted Oral Reference Dose (RfD) mg/kg/day (b) | Adult Intake Factor ($m^3$/kg/day) | | Daily Intake from Air (mg/kg/day) |
|---|---|---|---|---|---|---|
| | | | | Non-Threshold Compounds (Carcinogens) | Threshold Compounds (Non-carcinogens) | |

| dioxins and furans as PCDD and PCDF | 1.82E-14 | - | 9.89E-10 | | | 8.36E-15 |
| PAHs as benzo(a)pyrene* | 3.24E-09 | 0.5 | - | | | 6.17E-10 |

(a) WHO (2011) Guidelines for Drinking Water Quality. Fourth Edition. World Health Organization, Switzerland.
(b) DEH (2005) National Dioxins Program, Technical Report No. 12, Human Health Risk Assessment of Dioxins in Australia. Office of Chemical Safety, Australian Government Department of the Environment and Heritage, Canberra.

***Ingestion of Breastmilk***

$$Intake\ Factor = \frac{IR \times FM \times Ab \times EF \times ED}{BW \times AT}$$

$$Daily\ Intake = Cmilk_{fat} \times Intake\ Factor$$

| Parameter | Description and Units | Adopted Value (Child) | Notes |
|---|---|---|---|
| Intake Factor | Intake factor (kg/kg/day) | See model below | - |
| IR | Ingestion rate (kg/day) | 0.85 | enHealth (2012b). Suggested intake of breastmilk 850 mL/day for an infant less than 6-months of age. High end range of average intake. |
| FM | Fraction of Fat/Lipids in Milk (unitess) | 0.037 | DEH (2005) |
| Ab | Absorption Following Ingestion (unitless) | 0.9 | DEH (2005) |
| EF | Exposure frequency (days/year) | 365 | ASC NEPM (2013) - low to medium density residential |
| ED | Exposure duration (years) | 0.5 | Exposure time as an infant |
| BW | Body weight (kg) | 6 | Average weight of a 6-month old infant |
| AT | Averaging time - Non-threshold (days) | 25550 | ASC NEPM (2013) - low to medium density residential |
| | Averaging time -Threshold (days) | 365 | ASC NEPM (2013) - low to medium density residential |

| CoPC | Concentration of CoPC in milk fat (Cmilk fat) (mg/kg) | Child Intake Factor (kg/kg/day) | | Child Daily Intake (mg/kg/day) | |
|---|---|---|---|---|---|
| | | Non-Threshold Compounds (Carcinogens) | Threshold Compounds (Non-carcinogens) | Non-Threshold Compounds (Carcinogens) | Threshold Compounds (Non-carcinogens) |

# Adopted Toxicity Data - Inhalation Pathway

**Adopted Toxicity Data**

| Individual Compounds | Inhalation Unit Risk (IUR) (a) ($\mu g/m^3)^{-1}$ | Source | Reference Concentration (RfC) ($\mu g/m^3$) | Source | Background Exposure Allocation (%) | Source |
|---|---|---|---|---|---|---|
| antimony | - | - | 21 | RIVM (2008). Converted from TDI of 0.006 mg/kg/day. | 0% | Negligible. |
| arsenic | - | - | 1 | RIVM (2000). | 0% | ASC NEPM (2013). |
| cadmium | - | - | 0.005 | WHO (2000a). | 20% | ASC NEPM (2013). |
| chromium III | - | - | 0.1 | ATSDR (2008) | 0% | ASC NEPM (2013). Consistent with CrVI. |
| chromium VI | - | - | 0.1 | US EPA IRIS (2015). | 0% | ASC NEPM (2013). |
| lead | - | - | 0.5 | WHO (2000a). | 0% | Negligible. |
| manganese | - | - | 0.15 | WHO (2000b). | 20% | ASC NEPM (2013). |
| mercury | - | - | 0.2 | WHO (2003). | 10% | ASC NEPM (2013). |
| nickel | - | - | 0.02 | EA (2009). | 20% | ASC NEPM (2013). |
| cyanide | - | | 0.8 | USEPA (2010). | 0% | ASC NEPM (2013). |
| dioxins and furans as PCDD and PCDF | - | - | 0.00000805 | DEH (2005). Converted NHMRC TMI (70 pg/kg body weight/month) to TDI ($2.3 \times 10^{-9}$ mg/kg/day) to RfC. | 57% | DEH (2004) |
| PAHs as benzo(a)pyrene* | 8.70E-02 | WHO (2000b). TEF (1) | - | - | - | - |
| toluene | - | - | 5000 | US EPA IRIS (2015). | 0% | Friebel & Nadebaum (2011). |
| acetone (propanone) | - | - | 30900 | ATSDR (1994). Converted from chronic MRL of 13 ppm. | 10% | Friebel & Nadebaum (2011) (b) |
| benzene | 6.00E-06 | WHO (2010). | 30 | US EPA IRIS (2015). | 20% | Friebel & Nadebaum (2011). |
| Naphthalene* | - | - | 3.7 | ATSDR (2005) | 0% | Negligible. ATSDR (2005). |

**Notes**
CSF - Cancer slope factor.
RfD - Reference dose.
TDI - Tolerable daily intake.
TMI - Tolerable monthly intake.
(a) Those compounds with inhalation unit risk (IUR) values were considered to be carcinogens as part of this assessment. It should be noted that some compounds were assessed as both a carcinogen and non-carcinogen e.g. benzene.
(b) In absence of compound-specific background exposure data, the background exposure for semi or volatile CoPC has been set at 10% in accordance with the total petroleum hydrocarbon (TPH) background exposure allocation adopted by CRC CARE (2011) during derivation of the Health Screening Levels (HSLs).

**Potential Concentration in Soils Following Dust Deposition - Scenario 1 Grid Max**

**Site** Regain Tomago Facility
**Address** 638 Tomago Road, Tomago
**Client** Regain Services Pty Ltd

***Concentration in Soils***

$$C_s = \frac{DR \times (1 - e^{-k \times t})}{d \times \rho \times k} \times 1000$$

| Parameter | Description and Units | Adopted Value | | Notes |
|---|---|---|---|---|
| $C_s$ | Concentration of CoPC in soil (mg/kg) | See below | | Calculated using above equation (Stevens, 1991). |
| DR | Particle deposition rate for accidental release (mg/m$^2$/year) | See below | | Maximum modelled deposition rate for receptors combined. |
| k | Chemical-specific soil-loss constant (1/year) = ln(2)/$T^{0.5}$ | See below | | Calculated using equation ln(2)/$T^{0.5}$. |
| $T^{0.5}$ | Chemical half-life in soil (years) | See below | | Howard et al. (1991) for PAHs (benzo(a)pyrene) and hexachlorobenzene. NHMRC (2002) for dioxins and furans (surface soil). Conservative value adopted for heavy metals in the absense of published data. |
| t | Accumulation time (years) | 25 | | Emissions may occur for the assumed lifetime of the Facility. |
| d | Soil mixing depth (m) | 0.01 | 0.15 | It is assumed that the soil where deposition occurs is not well mixed (as would be the case in a garden or cultivated bed), and hence the mixing depth for depositied soils and dusts has been taken to be 1cm. For the assessment of potential plant uptake, a soil mixing zone of 15cm has been assumed within the root zone of plants. |
| ρ | Soil bulk-density (g/m$^3$) | 1.60E+06 | | Sandy soils (representative of surface soils) typically have bulk densities between 1.3 g/cm$^3$ to 1.7 g/cm$^3$ (McKenzie et al., 2004). In general, bulk densities greater than 1.6 g/cm$^3$ tend to restrict root growth. |
| 1000 | Conversion from g to kg | - | | |

| CoPC | Deposition Rate (total) (mg/m$^2$/year) | k (1/year) | $T^{0.5}$ (years) | $C_s$ (mg/kg) - Surface Soil | $C_s$ (mg/kg) - Soil-Plant Root Zone |

WHO, 2003. Antimony in Drinking Water. Background Document for Development of WHO Guidelines for Drinking Water Quality

For metals that were considered to be bioaccumulative and/or persistent, a conservative half-life value of 100 years was adopted in the absence of published data to account for the slow (or no) breakdown in the environment.

* Based on the Total PAH stack testing results collated from 2014 to 2016, the carcinogenic PAHs (Benzo(a)anthracene, Benzo(b+j)fluoranthene, Benzo(k)fluoranthene, Benzo(g,h,i)perylene, Chrysene, Dibenz(a,h)anthracene, and Indeno(1,2,3-c,d)pyrene) have been assessed as BaP, and the average percent contribution of the carcinogenic PAHs to the Total PAH is 0.67%. The speciated breakdowns of the Total PAH stack testing results are presented in

* Based on the Total PAH stack testing results collated from 2014 to 2016, the carcinogenic PAHs (Benzo(a)anthracene, Benzo(b+j)fluoranthene, Benzo(k)fluoranthene, Benzo(g,h,i)perylene, Chrysene, Dibenz(a,h)anthracene, and Indeno(1,2,3-c,d)pyrene) have been assessed as BaP, and the average percent contribution of the carcinogenic PAHs to the Total PAH is 0.67%. The remaining contribution of PAHs (99.3%) has been assessed as naphthalene. The speciated breakdowns of the Total PAH stack testing results are presented in Appendix G.

**Health Risk Calculations - Ingestion of Home-grown Produce - Scenario 1 Grid Max**

| | |
|---|---|
| **Site** | Regain Tomago Facility |
| **Address** | 638 Tomago Road, Tomago |
| **Client** | Regain Services Pty Ltd |
| **Scenario:** | Ingestion of Homegrown Produce by Off-site Residents (Adult and Child) |

***Concentration in Home-grown Produce***

*Deposited Material on Aboveground Plants*

$$C_p = \frac{DR \times F \times (1 - e^{-k \times t})}{Y \times k}$$

Refer to $C_o$ and $C_{ro}$ (mg/kg plant - wet weight). Although $C_o$ and $C_{ro}$ are presented as a wet weight, this is unlikely to affected the outcome of the assessment as dust deposition rates included both wet and dry deposition.

| Parameter | Description and Units | Adopted Value | Notes |
|---|---|---|---|
| $C_p$ | Concentration of CoPC in plant (mg/kg plant - wet weight) | See below | Calculated using above equation from HHRAP (Stevens, 1991). |
| DR | Particle deposition rate for accidental release (mg/m$^2$/day) | See below | Maximum modelled deposition rate for receptors combined. |
| F | Fraction for the surface area of plant (unitless) | 0.051 | For leafy aboveground crops, the surface area fraction (or plant interception fraction - how much of the depositing material remains on the plant) is estimated to be 0.051 (Stevens, 1991). |
| k | Chemical-specific loss constant for particles on plants (1/days) = ln(2)/T$^{0.5}$ | See below | Calculated using equation ln(2)/T$^{0.5}$. |
| T$^{0.5}$ | Chemical half-life on plant (days) | 14 | Weathering of particulates on plant surfaces does occur and in the absence of measured data, it is generally assumed that organics deposited onto the outer portion of plant surfaces have a weathering half-life of 14 days (Stevens, 1991). Conservative value adopted for heavy metals in the absense of published data. |
| t | Deposition time or length of growing season (days) | 70 | The growing season for typical aboveground plants varies, however it may be up to 70 days (i.e. tomatoes), which has been used in the calculation on concentrations during normal operations. |
| Y | Crop yield (kg/m$^2$) | 2 | Given that the residential areas surrounding the Site are typically urban low-density residential properties, the types of edible plant expected to be grown on the properties include tomatoes and beans. Corn, hay and wheat are not expected to be grown for human consumption in significant quantities in the area. For typical crops grown aboveground an average crop yield of 2 kg/m$^2$ has been adopted. |

| CoPC | DR (mg/m$^2$/day) | k (1/days) | $C_p$ (mg/kg plant - wet weight) |
|---|---|---|---|
| arsenic | 1.59E-11 | 4.95E-02 | 7.93E-12 |

| PAHs as benzo(a)pyrene* | 5.63E-11 | 4.95E-02 | 2.81E-11 |

*Uptake of Chemicals via Roots*

$$C_{rp} = C_s \times RUF$$

| Parameter | Description and Units | Adopted Value | Notes |
|---|---|---|---|
| $C_{rp}$ | Concentration of persistent CoPC in root of plant (mg/kg plant - wet weight) | See below | Calculated using above equation (US EPA, 2005). |
| $C_s$ | Concentration of persistent CoPC in soil assuming 15 cm mixing depth within gardens (mg/kg) | See below | Refer to Dust Deposition Model. |
| RUF | Root uptake factor (unitless) | See below | RAIS (Accessed 2018). Soil to wet plant uptake factor adopted. Value for 2,3,7,8-TCDD conservatively selected for dioxins and furans. |

| CoPC | Cs (mg/kg) - Soil-Plant Root Zone | RUF (unitless) | $C_{rp}$ (mg/kg plant - wet weight) |

**Health Risk Calculations - Ingestion of Poultry and Eggs - Scenario 1 Grid Max**

**Site** Regain Tomago Facility
**Address** 638 Tomago Road, Tomago
**Client** Regain Services Pty Ltd
**Scenario:** Ingestion of Poultry and Eggs by Off-site Residents (Adult and Child)

***Concentration in Eggs***

$$A_{egg} = [\Sigma(F_i \times Qpi \times Pi) + Qs \times Cs \times Bs] \times (Ba_{egg})$$

| Parameter | Description and Units | Adopted Value | Notes |
|---|---|---|---|
| $A_{egg}$ | Concentration of COPC in eggs (mg COPC/kg FW tissue) | See model below | Calculated using above equation. |
| $F_i$ | Fraction of plant type (i) (grain) grown on contaminated soil and ingested by the animal (chicken) (unitless) | 1 | Recommended by HHRAP (US EPA, 2005). Assumed 100% of the plant material eaten by chickens were grown on soil contaminated by emission sources. |
| $Qp_i$ | Quantity of plant type (i) (grain) eaten by the animal (chicken) each day (kg DW plant/day) | 0.2 | Recommended by HHRAP (US EPA, 2005). Estimated for grain feed only. |
| $P_i$ | Concentration of CoPC in plant type (i) (grain) eaten by the animal (chicken) (mg/kg DW) | See home-grown produce model | Refer to $C_p$ and $C_{rp}$ (mg/kg plant - wet weight). Although $C_p$ and $C_{rp}$ are presented as a wet weight, this is unlikely to affected the outcome of the assessment as dust deposition rates included both wet and dry deposition. |
| Qs | Quantity of soil eaten by the animal (chicken) (kg/day) | 0.022 | Recommended by HHRAP (US EPA, 2005). |
| Cs | Average soil concentration over exposure duration (mg CoPC/kg soil) | See dust-deposition model | Refer to $C_s$ Soil-Plant Root Zone (mg/kg) |
| Bs | Soil bioavailability factor (unitless) | 1 | Default value recommended by HHRAP (US EPA, 2005). |
| $Ba_{egg}$ | CoPC biotransfer factor for eggs (day/kg FW tissue) | See model below | The highest biotransfer factor for eggs recommended by the HHRAP Database (US EPA, 2005) or published by OEHHA (2015) was conservatively selected in the HHRA.<br>OEHHA values were adopted for arsenic, lead, mercury, nickel and dioxins and furans (value for 2,3,7,8-TCDD adopted for dioxins and furans).<br>HHRAP Database values were adopted for chromium and PAHs. For chromium, an egg biotransfer coefficient was not available and therefore fat transfer coefficients were estimated from the beef transfer coefficient. The egg biotransfer coefficient was then estimated by using the fat transfer coefficient and assumed that eggs contain a fat content of 8% consistent with US EPA (2005) and the following equations:<br>$Ba_{beef} = 10^{logBafat} \times 0.19$<br>$Ba_{egg} = 10^{logBafat} \times 0.08$ |

| CoPC | Concentration of CoPC in Plant (mg/kg DW) ($P_i$) | Cs (mg/kg) - Soil-Plant Root Zone | $A_{egg}$ | |
|---|---|---|---|---|
| | | | CoPC biotransfer factor for eggs ($Ba_{egg}$) (day/kg FW tissue) | Concentration of COPC in eggs ($A_{egg}$) (mg COPC/kg FW tissue) |
| arsenic | 7.95E-12 | 1.52E-12 | 7.00E-02 | 1.14E-13 |
| cadmium | 1.26E-10 | 2.35E-11 | 1.00E-02 | 2.57E-13 |
| chromium (total) | 7.69E-11 | 1.47E-11 | 2.32E-03 | 3.64E-14 |
| lead | 4.40E-11 | 8.41E-12 | 4.00E-02 | 3.59E-13 |

**Scenario:** Ingestion of Homegrown Beef by Off-site Residents (Adult and Child)

***Concentration in Beef***

$$A_{beef} = [\Sigma(F_i \times Qpi \times Pi) + Qs \times Cs \times Bs] \times Ba_{beef} \times MF$$

| Parameter | Description and Units | Adopted Value | Notes |
|---|---|---|---|
| $A_{beef}$ | Concentration of CoPC in beef through ingestion of contaminated feed items (plant) and soil (mg CoPC/kg FW tissue) | See model below | Calculated using above equation. |
| $F_i$ | Fraction of plant type (i) grown on contaminated soil and ingested by the animal (cattle) (unitless) | 1 | Recommended by HHRAP (US EPA, 2005). Assumed 100% of the plant material eaten by cattle were grown on soil contaminated by emission sources. |
| $Qp_i$ | Quantity of plant type (i) eaten by the animal (cattle) per day (kg DW plant/day) | 11.8 | Recommended by HHRAP (US EPA, 2005). Sum of beef ingestion rates for forage (8.8 kg DW/day), silage (2.5 kg DW/day) and grain (0.47 kg DW/day). |
| $P_i$ | Concentration of CoPC in each plant type (i) eaten by the animal (cattle) (mg/kg DW) | See home-grown produce model | Refer to $C_p$ and $C_{rp}$ (mg/kg plant - wet weight). Although $C_p$ and $C_{rp}$ are presented as a wet weight, this is unlikely to affected the outcome of the assessment |
| Qs | Quantity of soil eaten by the animal (cattle) each day (kg/day) | 0.5 | Recommended by HHRAP (US EPA, 2005). |
| Cs | Average soil concentration over exposure duration (mg CoPC/kg soil) | See dust-deposition model | Refer to $C_s$ Soil-Plant Root Zone (mg/kg) |
| Bs | Soil bioavailability factor (unitless) | 1 | Default value recommended by HHRAP (US EPA, 2005). |
| $Ba_{beef}$ | CoPC biotransfer factor for beef (day/kg FW tissue) | See model below | The highest biotransfer factor for beef recommended by the HHRAP Database (US EPA, 2005) or published in RAIS (2015) was conservatively selected in the HHRA.<br>RAIS values were adopted for all metals.<br>HHRAP Database values were adopted for dioxins and furans (value for 2,3,7,8-TCDD adopted for dioxins and furans) and PAHs |
| MF | Metabolism factor (unitless) | 1 | Default value recommended by HHRAP (US EPA, 2005). |

| CoPC | Concentration of CoPC in Plant (mg/kg DW) ($P_i$) | Cs (mg/kg) - Soil-Plant Root Zone | CoPC biotransfer factor for beef $Ba_{beef}$ (day/kg FW tissue) | Concentration of CoPC in beef through ingestion of contaminated feed items (plant) and soil |
|---|---|---|---|---|
| arsenic | 7.95E-12 | 1.52E-12 | 0.002 | 1.89E-13 |

***Ingestion of Beef***

$$Intake\ Factor = \frac{IR \times FI \times ME \times EF \times ED}{BW \times AT}$$

$$Daily\ Intake = Abeef \times Intake\ Factor$$

| Parameter | Description and Units | Adopted Value | | Notes |
|---|---|---|---|---|
| | | Adult | Child | |
| Intake Factor | Intake factor (kg/kg/day) | See model below | | - |
| IR | Ingestion rate (kg/day) | 0.16 | 0.06 | enHealth (2012b). Suggested (average) values for intake of total meat. Value for >19 years adopted for an adult (160 g/day) and 2-3 years adopted for a child (60 g/day). |
| FI | Fraction ingested from home-grown source (unitess) | 0.01 | | Assumed less than 1% of beef sourced from adjacent site ingested as a conservative estimate |
| ME | Matrix effect (unitless) | 1 | | Assumed 100% bioavailability |
| EF | Exposure frequency (days/year) | 365 | 365 | ASC NEPM (2013) - low to medium density residential |
| ED | Exposure duration (years) | 29 | 6 | ASC NEPM (2013) - low to medium density residential |
| BW | Body weight (kg) | 70 | 15 | ASC NEPM (2013) - low to medium density residential |
| AT | Averaging time - Non-threshold (days) | 25550 | 25550 | ASC NEPM (2013) - low to medium density residential |
| | Averaging time -Threshold (days) | 10585 | 2190 | ASC NEPM (2013) - low to medium density residential |

**Health Risk Calculations - Ingestion of Breastmilk - Scenario 1 Grid Max**

**Site** Regain Tomago Facility
**Address** 638 Tomago Road, Tomago
**Client** Regain Services Pty Ltd
**Scenario:** Ingestion of Breastmilk by Off-site Residents (Child)

***Concentration in Breastmilk***

$$C_{milk\ fat} = \frac{m \times h \times f_1}{0.693 \times f_2}$$

| Parameter | Description and Units | Adopted Value | Notes |
|---|---|---|---|
| $C_{milk\ fat}$ | Concentration of CoPC in milk fat (mg/kg) | See model below | - |
| m | Average maternal intake (mg/kg/day) | See model below | The potential maternal intake is a highly variable parameter in the above equation. It can be assumed that the calculations undertaken to calculate adult intake of each CoPC via inhalation and ingestion are relevant for a mother who may be breastfeeding an infant. |
| h | Half-life of chemical in body, adults (days) | See model below | Value from NHMRC (2002) for dioxins and furans. Value from HSDB online database for PAHs (current to 2010). Value from WHO (2011), NHMRC (2016) or the HSDB online database for most metals. For mercury, the biological half-life is stated to be 'many years', which was assumed to be 10 years. |
| $f_1$ | Fraction of ingested chemical stored in fat (unitless) | 0.9 | No data is available that is specific to the fraction of organic chemicals that may be stored as fat and hence available data for dioxins has been adopted. The fraction of ingested organic chemicals which is stored as fat is recommended to be 0.9 (US EPA, 1998). |
| $f_2$ | Fraction of mothers weight that is fat (unitless) | 0.35 | The recommended fraction of mother's body weight which is fat is 0.35 (for females in south-eastern urban areas of Australia aged 31 to 45 years (DEH, 2005)). |

| CoPC | Adult intake from air, soil (ingestion and dermal contact), home-grown, produce, eggs and beef (m) (mg/kg/day) | Half-life of chemical in body, adults (h) (days) | Concentration of CoPC in milk fat ($C_{milk\ fat}$) (mg/kg) |
|---|---|---|---|
| arsenic | 5.61E-09 | 60 | 1.25E-06 |
| cadmium | 8.68E-08 | 5475 | 1.76E-03 |
| chromium (total) | 5.42E-08 | 83.4 | 1.68E-05 |
| lead | 3.10E-08 | 10950 | 1.26E-03 |
| mercury | 5.15E-09 | 3650 | 6.97E-05 |
| nickel | 1.17E-07 | 1.8 | 7.79E-07 |
| dioxins and furans as PCDD and PCDF | 1.12E-13 | 2555 | 1.06E-09 |
| PAHs as benzo(a)pyrene* | 8.24E-09 | 5.5 | 1.68E-07 |

***Daily Intake from Air***

$$Intake\ Factor = \frac{InhR \times ET \times FI \times EF \times ED}{BW \times AT}$$

| Parameter | Description and Units | Adopted Value (Adult) | Notes |
|---|---|---|---|
| Intake Factor | Intake factor ($m^3$/kg/day) | See model below | - |
| InhR | Inhalation Rate ($m^3$/hour) | 1.34 | Inhalation rate assuming 20 hours indoors at 1.17 $m^3$/hour and 4 hours outdoors at 2.2 $m^3$/hour. |
| ET | Exposure time (hours/day) | 24 | ASC NEPM (2013) - low to medium density residential. |
| FI | Fraction inhaled from contamination source (unitless) | 1 | Assumed intake from contamination source for the whole ET. |
| EF | Exposure frequency (days/year) | 365 | ASC NEPM (2013) - low to medium density residential |
| ED | Exposure duration (years) | 29 | ASC NEPM (2013) - low to medium density residential |
| BW | Body weight (kg) | 70 | ASC NEPM (2013) - low to medium density residential |
| AT | Averaging time - Non-threshold (days) | 25550 | ASC NEPM (2013) - low to medium density residential |
| | Averaging time -Threshold (days) | 10585 | ASC NEPM (2013) - low to medium density residential |

| CoPC | Grid Maximum GLC (mg/$m^3$) | Non-Threshold Slope Factor (mg/kg/day)$^{-1}$ (a) | Background Adjusted Oral Reference Dose (RfD) mg/kg/day (b) | Adult Intake Factor ($m^3$/kg/day) | | Daily Intake from Air (mg/kg/day) |
|---|---|---|---|---|---|---|
| | | | | Non-Threshold Compounds (Carcinogens) | Threshold Compounds (Non-carcinogens) | |
| arsenic | 1.22E-08 | - | 1.00E-03 | 0.19 | 0.46 | 5.61E-09 |
| cadmium | 1.89E-07 | - | 3.20E-04 | | | 8.68E-08 |
| chromium (total) | 1.18E-07 | - | 9.00E-04 | | | 5.42E-08 |
| lead | 6.74E-08 | - | 3.50E-03 | | | 3.10E-08 |
| mercury | 1.12E-08 | - | 3.60E-04 | | | 5.15E-09 |
| nickel | 2.54E-07 | - | 4.80E-03 | | | 1.17E-07 |
| dioxins and furans as PCDD and PCDF | 2.43E-13 | - | 9.89E-10 | | | 1.12E-13 |
| PAHs as benzo(a)pyrene* | 4.33E-08 | 0.5 | - | | | 8.24E-09 |

(a) WHO (2011) Guidelines for Drinking Water Quality. Fourth Edition. World Health Organization, Switzerland.

# Adopted Toxicity Data - Inhalation Pathway

**Adopted Toxicity Data**

| Individual Compounds | Inhalation Unit Risk (IUR) (a) ($\mu g/m^3)^{-1}$ | Source | Reference Concentration (RfC) ($\mu g/m^3$) | Source | Background Exposure Allocation (%) | Source |
|---|---|---|---|---|---|---|
| antimony | - | - | 21 | RIVM (2008). Converted from TDI of 0.006 mg/kg/day. | 0% | Negligible. |
| arsenic | - | - | 1 | RIVM (2000). | 0% | ASC NEPM (2013). |
| cadmium | - | - | 0.005 | WHO (2000a). | 20% | ASC NEPM (2013). |
| chromium III | - | - | 0.1 | ATSDR (2008) | 0% | ASC NEPM (2013). Consistent with CrVI. |
| chromium VI | - | - | 0.1 | US EPA IRIS (2015). | 0% | ASC NEPM (2013). |
| lead | - | - | 0.5 | WHO (2000a). | 0% | Negligible. |
| manganese | - | - | 0.15 | WHO (2000b). | 20% | ASC NEPM (2013). |
| mercury | - | - | 0.2 | WHO (2003). | 10% | ASC NEPM (2013). |
| nickel | - | - | 0.02 | EA (2009). | 20% | ASC NEPM (2013). |
| cyanide | - | | 0.8 | USEPA (2010). | 0% | ASC NEPM (2013). |
| Dioxins and furans (PCDDs and PCDFs) | - | - | 0.00000805 | DEH (2005). Converted NHMRC TMI (70 pg/kg body weight/month) to TDI ($2.3 \times 10^{-9}$ mg/kg/day) to RfC. | 57% | DEH (2004) |
| PAHs as benzo(a)pyrene* | 8.70E-02 | WHO (2000b). TEF (1) | - | - | - | - |
| toluene | - | - | 5000 | US EPA IRIS (2015). | 0% | Friebel & Nadebaum (2011). |
| acetone (propanone) | - | - | 30900 | ATSDR (1994). Converted from chronic MRL of 13 ppm. | 10% | Friebel & Nadebaum (2011) (b) |
| benzene | 6.00E-06 | WHO (2010). | 30 | US EPA IRIS (2015). | 20% | Friebel & Nadebaum (2011). |
| Naphthalene* | - | - | 3.7 | ATSDR (2005) | 0% | Negligible. ATSDR (2005). |

**Notes**
CSF - Cancer slope factor.
RfD - Reference dose.
TDI - Tolerable daily intake.
TMI - Tolerable monthly intake.
(a) Those compounds with inhalation unit risk (IUR) values were considered to be carcinogens as part of this assessment. It should be noted that some compounds were assessed as both a carcinogen and non-carcinogen e.g. benzene.
(b) In absence of compound-specific background exposure data, the background exposure for semi or volatile CoPC has been set at 10% in accordance with the total petroleum hydrocarbon (TPH) background exposure allocation adopted by CRC CARE (2011) during derivation of the Health Screening Levels (HSLs).

* Based on the Total PAH stack testing results collated from 2014 to 2016, the carcinogenic PAHs (Benzo(a)anthracene, Benzo(b+j)fluoranthene, Benzo(k)fluoranthene, Benzo(g,h,i)perylene, Chrysene, Dibenz(a,h)anthracene, and Indeno(1,2,3-c,d)pyrene) have been assessed as BaP, and the average percent contribution of the carcinogenic PAHs to the Total PAH is 0.67%. The remaining contribution of PAHs (99.3%) has been assessed as naphthalene. The speciated breakdowns of the Total PAH stack testing results are presented in Appendix G.

* Based on the Total PAH stack testing results collated from 2014 to 2016, the carcinogenic PAHs (Benzo(a)anthracene, Benzo(b+j)fluoranthene, Benzo(k)fluoranthene, Benzo(g,h,i)perylene, Chrysene, Dibenz(a,h)anthracene, and Indeno(1,2,3-c,d)pyrene) have been assessed as BaP, and the average percent contribution of the carcinogenic PAHs to the Total PAH is 0.67%. The remaining contribution of PAHs (99.3%) has been assessed as naphthalene. The speciated breakdowns of the Total PAH stack testing results are presented in Appendix G.

# Risk Estimate for Recreational User - Inhalation Pathway (Scenario 2)

**Health Risk Calculations - Inhalation of Vapour - Scenario 2**

**Site** Regain Tomago Facility
**Address** 638 Tomago Road, Tomago
**Client** Regain Services Pty Ltd
**Scenario:** Inhalation of Vapour by Off-site Recreational Users (Adult and Child)

$$Exposure\ Adjusted\ Air\ Concentration\left(\frac{\mu g}{m^3}\right) = \frac{Cair\ \left(\frac{\mu g}{m^3}\right) \times ET\ \left(\frac{h}{d}\right) \times EF\ \left(\frac{d}{y}\right) \times ED(y)}{AT(h)}$$

| Parameter | Description and Units | Adopted Value | | Notes |
|---|---|---|---|---|
| | | Adult | Child | |
| Cair | Chemical concentration in air (µg/m$^3$) | See model below | | Grid maximum ground level concentration (GLC) |

* Based on the Total PAH stack testing results collated from 2014 to 2016, the carcinogenic PAHs (Benzo(a)anthracene, Benzo(b+j)fluoranthene, Benzo(k)fluoranthene, Benzo(g,h,i)perylene, Chrysene, Dibenz(a,h)anthracene, and Indeno(1,2,3-c,d)pyrene) have been assessed as BaP, and the average percent contribution of the carcinogenic PAHs to the Total PAH is 0.67%. The remaining contribution of PAHs (99.3%) has been assessed as naphthalene. The speciated breakdowns of the Total PAH stack testing results are presented in Appendix G.

**Potential Concentration in Soils Following Dust Deposition (Scenario 2)**

**Site** Regain Tomago Facility
**Address** 638 Tomago Road, Tomago
**Client** Regain Services Pty Ltd

***Concentration in Soils***

$$C_s = \frac{DR \times (1 - e^{-k \times t})}{d \times \rho \times k} \times 1000$$

| Parameter | Description and Units | Adopted Value | | Notes |
|---|---|---|---|---|
| $C_s$ | Concentration of CoPC in soil (mg/kg) | See below | | Calculated using above equation (Stevens, 1991). |
| DR | Particle deposition rate for accidental release (mg/m$^2$/year) | See below | | Maximum modelled deposition rate for receptors combined. |
| k | Chemical-specific soil-loss constant (1/year) = ln(2)/$T^{0.5}$ | See below | | Calculated using equation ln(2)/$T^{0.5}$. |
| $T^{0.5}$ | Chemical half-life in soil (years) | See below | | Howard et al. (1991) for PAHs (benzo(a)pyrene). NHMRC (2002) for dioxins and furans (surface soil). Conservative value adopted for heavy metals in the absense of published data. |
| t | Accumulation time (years) | 25 | | Emissions may occur for the assumed lifetime of the Facility. |
| d | Soil mixing depth (m) | 0.01 | 0.15 | It is assumed that the soil where deposition occurs is not well mixed (as would be the case in a garden or cultivated bed), and hence the mixing depth for depositied soils and dusts has been taken to be 1cm. For the assessment of potential plant uptake, a soil mixing zone of 15cm has been assumed within the root zone of plants. |
| ρ | Soil bulk-density (g/m$^3$) | 1.60E+06 | | Sandy soils (representative of surface soils) typically have bulk densities between 1.3 g/cm$^3$ to 1.7 g/cm$^3$ (McKenzie et al., 2004). In general, bulk densities greater than 1.6 g/cm$^3$ tend to restrict root growth. |
| 1000 | Conversion from g to kg | - | | |

| CoPC | Deposition Rate (total) (mg/m$^2$/year) | k (1/year) | $T^{0.5}$ (years) | $C_s$ (mg/kg) - Surface Soil | $C_s$ (mg/kg) - Soil-Plant Root Zone |
|---|---|---|---|---|---|
| antimony | | Not bioaccumulative (WHO, 2003) | | | |

WHO, 2003. Antimony in Drinking Water. Background Document for Development of WHO Guidelines for Drinking Water Quality

For metals that were considered to be bioaccumulative and/or persistent, a conservative half-life value of 100 years was adopted in the absence of published data to account for the slow (or no) breakdown in the environment.

* Based on the Total PAH stack testing results collated from 2014 to 2016, the carcinogenic PAHs (Benzo(a)anthracene, Benzo(b+j)fluoranthene, Benzo(k)fluoranthene, Benzo(g,h,i)perylene, Chrysene, Dibenz(a,h)anthracene, and Indeno(1,2,3-c,d)pyrene) have been assessed as BaP, and the average percent contribution of the carcinogenic PAHs to the Total PAH is 0.67%. The remaining contribution of PAHs (99.3%) has been assessed as naphthalene. The speciated breakdowns of the Total PAH stack testing results are presented in Appendix G.

**Health Risk Calculations - Ingestion of Home-grown Produce (Scenario 2)**

| | |
|---|---|
| **Site** | Regain Tomago Facility |
| **Address** | 638 Tomago Road, Tomago |
| **Client** | Regain Services Pty Ltd |
| **Scenario:** | Ingestion of Homegrown Produce by Off-site Residents (Adult and Child) |

***Concentration in Home-grown Produce***

*Deposited Material on Aboveground Plants*

$$C_p = \frac{DR \times F \times (1 - e^{-k \cdot t})}{Y \times k}$$

| Parameter | Description and Units | Adopted Value | Notes |
|---|---|---|---|
| $C_p$ | Concentration of CoPC in plant (mg/kg plant - wet weight) | See below | Calculated using above equation from HHRAP (Stevens, 1991). |
| DR | Particle deposition rate for accidental release (mg/m$^2$/day) | See below | Maximum modelled deposition rate for receptors combined. |
| F | Fraction for the surface area of plant (unitless) | 0.051 | For leafy aboveground crops, the surface area fraction (or plant interception fraction - how much of the depositing material remains on the plant) is estimated to be 0.051 (Stevens, 1991). |
| k | Chemical-specific loss constant for particles on plants (1/days) = ln(2)/T$^{0.5}$ | See below | Calculated using equation ln(2)/T$^{0.5}$. |
| T$^{0.5}$ | Chemical half-life on plant (days) | 14 | Weathering of particulates on plant surfaces does occur and in the absence of measured data, it is generally assumed that organics deposited onto the outer portion of plant surfaces have a weathering half-life of 14 days (Stevens, 1991). Conservative value adopted for heavy metals in the absense of published data. |
| t | Deposition time or length of growing season (days) | 70 | The growing season for typical aboveground plants varies, however it may be up to 70 days (i.e. tomatoes), which has been used in the calculation on concentrations during normal operations. |
| Y | Crop yield (kg/m$^2$) | 2 | Given that the residential areas surrounding the Site are typically urban low-density residential properties, the types of edible plant expected to be grown on the properties include tomatoes and beans. Corn, hay and wheat are not expected to be grown for human consumption in significant quantities in the area. For typical crops grown aboveground an average crop yield of 2 kg/m$^2$ has been adopted. |

| CoPC | DR (mg/m$^2$/day) | k (1/days) | $C_p$ (mg/kg plant - wet weight) |
|---|---|---|---|
| arsenic | 1.05E-10 | 4.95E-02 | 5.24E-11 |
| cadmium | 2.93E-10 | 4.95E-02 | 1.46E-10 |
| chromium | 9.64E-10 | 4.95E-02 | 4.81E-10 |

| PAHs as benzo(a)pyrene* | 4.00E-11 | 4.95E-02 | 2.00E-11 |

*Uptake of Chemicals via Roots*

$$C_{rp} = C_s \times RUF$$

| Parameter | Description and Units | Adopted Value | Notes |
|---|---|---|---|
| $C_{rp}$ | Concentration of persistent CoPC in root of plant (mg/kg plant - wet weight) | See below | Calculated using above equation (US EPA, 2005). |
| $C_s$ | Concentration of persistent CoPC in soil assuming 15 cm mixing depth within gardens (mg/kg) | See below | Refer to Dust Deposition Model. |
| RUF | Root uptake factor (unitless) | See below | RAIS (Accessed 2018). Soil to wet plant uptake factor adopted. Value for 2,3,7,8-TCDD conservatively selected for dioxins and furans. |

| CoPC | Cs (mg/kg) - Soil-Plant Root Zone | RUF (unitless) | $C_{rp}$ (mg/kg plant - wet weight) |
|---|---|---|---|
| arsenic | 1.00E-11 | 1.00E-02 | 1.00E-13 |

**Address** 638 Tomago Road, Tomago
**Client** Regain Services Pty Ltd
**Scenario:** Ingestion of Poultry and Eggs by Off-site Residents (Adult and Child)

***Concentration in Eggs***

$$A_{egg} = [\Sigma(F_i \times Qpi \times Pi) + Qs \times Cs \times Bs] \times (Ba_{egg})$$

| Parameter | Description and Units | Adopted Value | Notes |
|---|---|---|---|
| $A_{egg}$ | Concentration of COPC in eggs (mg COPC/kg FW tissue) | See model below | Calculated using above equation. |
| $F_i$ | Fraction of plant type (i) (grain) grown on contaminated soil and ingested by the animal (chicken) (unitless) | 1 | Recommended by HHRAP (US EPA, 2005). Assumed 100% of the plant material eaten by chickens were grown on soil contaminated by emission sources. |
| $Qp_i$ | Quantity of plant type (i) (grain) eaten by the animal (chicken) each day (kg DW plant/day) | 0.2 | Recommended by HHRAP (US EPA, 2005). Estimated for grain feed only. |
| $P_i$ | Concentration of CoPC in plant type (i) (grain) eaten by the animal (chicken) (mg/kg DW) | See home-grown produce model | Refer to $C_p$ and $C_{rp}$ (mg/kg plant - wet weight). Although $C_p$ and $C_{rp}$ are presented as a wet weight, this is unlikely to affected the outcome of the assessment as dust deposition rates included both wet and dry deposition. |
| Qs | Quantity of soil eaten by the animal (chicken) (kg/day) | 0.022 | Recommended by HHRAP (US EPA, 2005). |
| Cs | Average soil concentration over exposure duration (mg CoPC/kg soil) | See dust-deposition model | Refer to $C_s$ Soil-Plant Root Zone (mg/kg) |
| Bs | Soil bioavailability factor (unitless) | 1 | Default value recommended by HHRAP (US EPA, 2005). |
| $Ba_{egg}$ | CoPC biotransfer factor for eggs (day/kg FW tissue) | See model below | The highest biotransfer factor for eggs recommended by the HHRAP Database (US EPA, 2005) or published by OEHHA (2015) was conservatively selected in the HHRA.<br>OEHHA values were adopted for arsenic, lead, mercury, nickel and dioxins and furans (value for 2,3,7,8-TCDD adopted for dioxins and furans).<br>HHRAP Database values were adopted for chromium and PAHs. For chromium, an egg biotransfer coefficient was not available and therefore fat transfer coefficients were estimated from the beef transfer coefficient. The egg biotransfer coefficient was then estimated by using the fat transfer coefficient and assumed that eggs contain a fat content of 8% consistent with US EPA (2005) and the following equations:<br>$Ba_{beef} = 10^{logBafat} \times 0.19$<br>$Ba_{egg} = 10^{logBafat} \times 0.08$ |

| CoPC | Concentration of CoPC in Plant (mg/kg DW) ($P_i$) | Cs (mg/kg) - Soil-Plant Root Zone | $A_{egg}$ | |
|---|---|---|---|---|
| | | | CoPC biotransfer factor for eggs ($Ba_{egg}$) (day/kg FW tissue) | Concentration of COPC in eggs ($A_{egg}$) (mg COPC/kg FW tissue) |
| arsenic | 5.25E-11 | 1.00E-11 | 7.00E-02 | 7.50E-13 |
| cadmium | 1.50E-10 | 2.80E-11 | 1.00E-02 | 3.06E-13 |
| chromium | 4.81E-10 | 9.22E-11 | 2.32E-03 | 2.28E-13 |
| lead | 2.77E-10 | 5.29E-11 | 4.00E-02 | 2.26E-12 |
| mercury | 4.75E-11 | 8.72E-12 | 8.00E-01 | 7.75E-12 |
| nickel | 1.03E-09 | 1.97E-10 | 2.00E-02 | 4.21E-12 |
| dioxins and furans as PCDD and PCDF | 5.94E-16 | 7.35E-17 | 1.00E+01 | 1.20E-15 |
| PAHs as benzo(a)pyrene* | 2.00E-11 | 3.49E-13 | 1.58E+00 | 6.33E-12 |

***Ingestion of Eggs***

$$Intake\ Factor = \frac{IR \times FI \times ME \times EF \times ED}{BW \times AT}$$

$$Daily\ Intake = Aegg \times Intake\ Factor$$

| Parameter | Description and Units | Adopted Value | | Notes |
|---|---|---|---|---|
| | | Adult | Child | |
| Intake Factor | Intake factor (kg/kg/day) | See model below | | - |
| IR | Ingestion rate (kg/day) | 0.014 | 0.006 | enHealth (2012b). Suggested (average) values for intake of total egg. Value for >19 years adopted for an adult (14 g/day) and 2-3 years adopted for a child (6 g/day). |
| FI | Fraction ingested from home-grown source (unitless) | 1 | | 100% home-sourced eggs as a conservative estimate |
| ME | Matrix effect (unitless) | 1 | | Assumed 100% bioavailability |
| EF | Exposure frequency (days/year) | 365 | 365 | ASC NEPM (2013) - low to medium density residential |
| ED | Exposure duration (years) | 29 | 6 | ASC NEPM (2013) - low to medium density residential |
| BW | Body weight (kg) | 70 | 15 | ASC NEPM (2013) - low to medium density residential |

**Health Risk Calculations - Ingestion of Homegrown Beef (Scenario 2)**
**Site** Regain Tomago Facility
**Address** 638 Tomago Road, Tomago
**Client** Regain Services Pty Ltd
**Scenario:** Ingestion of Homegrown Beef by Off-site Residents (Adult and Child)

***Concentration in Beef***

$$A_{beef} = [\Sigma(F_i \times Qpi \times Pi) + Qs \times Cs \times Bs] \times Ba_{beef} \times MF$$

| Parameter | Description and Units | Adopted Value | Notes |
|---|---|---|---|
| $A_{beef}$ | Concentration of CoPC in beef through ingestion of contaminated feed items (plant) and soil (mg CoPC/kg FW tissue) | See model below | Calculated using above equation. |
| $F_i$ | Fraction of plant type (i) grown on contaminated soil and ingested by the animal (cattle) (unitless) | 1 | Recommended by HHRAP (US EPA, 2005). Assumed 100% of the plant material eaten by cattle were grown on soil contaminated by emission sources. |
| $Qp_i$ | Quantity of plant type (i) eaten by the animal (cattle) per day (kg DW plant/day) | 11.8 | Recommended by HHRAP (US EPA, 2005). Sum of beef ingestion rates for forage (8.8 kg DW/day), silage (2.5 kg DW/day) and grain (0.47 kg DW/day). |
| $P_i$ | Concentration of CoPC in each plant type (i) eaten by the animal (cattle) (mg/kg DW) | See home-grown produce model | Refer to $C_p$ and $C_{rp}$ (mg/kg plant - wet weight). Although $C_p$ and $C_{rp}$ are presented as a wet weight, this is unlikely to affected the outcome of the assessment as dust deposition rates included both wet and dry deposition. |
| Qs | Quantity of soil eaten by the animal (cattle) each day (kg/day) | 0.5 | Recommended by HHRAP (US EPA, 2005). |
| Cs | Average soil concentration over exposure duration (mg CoPC/kg soil) | See dust-deposition model | Refer to $C_s$ Soil-Plant Root Zone (mg/kg) |
| Bs | Soil bioavailability factor (unitless) | 1 | Default value recommended by HHRAP (US EPA, 2005). |
| $Ba_{beef}$ | CoPC biotransfer factor for beef (day/kg FW tissue) | See model below | The highest biotransfer factor for beef recommended by the HHRAP Database (US EPA, 2005) or published in RAIS (2015) was conservatively selected in the HHRA.<br>RAIS values were adopted for all metals.<br>HHRAP Database values were adopted for dioxins and furans (value for 2,3,7,8-TCDD adopted for dioxins and furans) and PAHs |
| MF | Metabolism factor (unitless) | 1 | Default value recommended by HHRAP (US EPA, 2005). |

| CoPC | Concentration of CoPC in Plant (mg/kg DW) ($P_i$) | Cs (mg/kg) - Soil-Plant Root Zone | CoPC biotransfer factor for beef $Ba_{beef}$ (day/kg FW tissue) | Concentration of CoPC in beef through ingestion of contaminated feed items (plant) and soil |
|---|---|---|---|---|
| arsenic | 5.25E-11 | 1.00E-11 | 0.002 | 1.25E-12 |
| cadmium | 1.50E-10 | 2.80E-11 | 0.00055 | 9.79E-13 |

**Health Risk Calculations - Ingestion of Breastmilk (Scenario 2)**

**Site** Regain Tomago Facility
**Address** 638 Tomago Road, Tomago
**Client** Regain Services Pty Ltd
**Scenario:** Ingestion of Breastmilk by Off-site Residents (Child)

***Concentration in Breastmilk***

$$C_{milk\ fat} = \frac{m \times h \times f_1}{0.693 \times f_2}$$

| Parameter | Description and Units | Adopted Value | Notes |
|---|---|---|---|
| $C_{milk\ fat}$ | Concentration of CoPC in milk fat (mg/kg) | See model below | - |
| m | Average maternal intake (mg/kg/day) | See model below | The potential maternal intake is a highly variable parameter in the above equation. It can be assumed that the calculations undertaken to calculate adult intake of each CoPC via inhalation and ingestion are relevant for a mother who may be breastfeeding an infant. |
| h | Half-life of chemical in body, adults (days) | See model below | Value from NHMRC (2002) for dioxins and furans. Value from HSDB online database for PAHs (current to 2010). Value from WHO (2011), NHMRC (2016) or the HSDB online database for most metals. For mercury, the biological half-life is stated to be 'many years', which was assumed to be 10 years. |
| $f_1$ | Fraction of ingested chemical stored in fat (unitless) | 0.9 | No data is available that is specific to the fraction of organic chemicals that may be stored as fat and hence available data for dioxins has been adopted. The fraction of ingested organic chemicals which is stored as fat is recommended to be 0.9 (US EPA, 1998). |
| $f_2$ | Fraction of mothers weight that is fat (unitless) | 0.35 | The recommended fraction of mother's body weight which is fat is 0.35 (for females in south-eastern urban areas of Australia aged 31 to 45 years (DEH, 2005)). |

| CoPC | Adult intake from air, soil (ingestion and dermal contact), home-grown, produce, eggs and beef (m) (mg/kg/day) | Half-life of chemical in body, adults (h) (days) | Concentration of CoPC in milk fat ($C_{milk\ fat}$) (mg/kg) |
|---|---|---|---|
| arsenic | 1.45E-08 | 60 | 3.23E-06 |
| cadmium | 4.03E-08 | 5475 | 8.19E-04 |
| chromium | 1.33E-07 | 83.4 | 4.11E-05 |
| lead | 7.63E-08 | 10950 | 3.10E-03 |
| mercury | 1.25E-08 | 3650 | 1.70E-04 |
| nickel | 2.83E-07 | 1.8 | 1.89E-06 |
| dioxins and furans as PCDD and PCDF | 1.64E-13 | 2555 | 1.56E-09 |
| PAHs as benzo(a)pyrene* | 2.28E-09 | 5.5 | 4.66E-08 |

***Daily Intake from Air***

$$Intake\ Factor = \frac{InhR \times ET \times FI \times EF \times ED}{BW \times AT}$$

| Parameter | Description and Units | Adopted Value (Adult) | Notes |
|---|---|---|---|
| Intake Factor | Intake factor ($m^3$/kg/day) | See model below | - |
| InhR | Inhalation Rate ($m^3$/hour) | 1.34 | Inhalation rate assuming 20 hours indoors at 1.17 $m^3$/hour and 4 hours outdoors at 2.2 $m^3$/hour. |
| ET | Exposure time (hours/day) | 24 | ASC NEPM (2013) - low to medium density residential. |
| FI | Fraction inhaled from contamination source (unitless) | 1 | Assumed intake from contamination source for the whole ET. |
| EF | Exposure frequency (days/year) | 365 | ASC NEPM (2013) - low to medium density residential |
| ED | Exposure duration (years) | 29 | ASC NEPM (2013) - low to medium density residential |
| BW | Body weight (kg) | 70 | ASC NEPM (2013) - low to medium density residential |
| AT | Averaging time - Non-threshold (days) | 25550 | ASC NEPM (2013) - low to medium density residential |
| | Averaging time -Threshold (days) | 10585 | ASC NEPM (2013) - low to medium density residential |

| CoPC | Maximum GLC (mg/$m^3$) | Non-Threshold Slope Factor (mg/kg/day)$^{-1}$ (a) | Background Adjusted Oral Reference Dose (RfD) mg/kg/day (b) | Adult Intake Factor ($m^3$/kg/day) | | Daily Intake from Air (mg/kg/day) |
|---|---|---|---|---|---|---|
| | | | | Non-Threshold Compounds (Carcinogens) | Threshold Compounds (Non-carcinogens) | |
| arsenic | 3.16E-08 | - | 1.00E-03 | 0.19 | 0.46 | 1.45E-08 |
| cadmium | 8.78E-08 | - | 3.20E-04 | | | 4.03E-08 |
| chromium | 2.89E-07 | - | 9.00E-04 | | | 1.33E-07 |
| lead | 1.66E-07 | - | 3.50E-03 | | | 7.63E-08 |

# Adopted Toxicity Data - Inhalation Pathway

**Adopted Toxicity Data**

| Individual Compounds | Inhalation Unit Risk (IUR) (a) ($\mu g/m^3)^{-1}$ | Source | Reference Concentration (RfC) ($\mu g/m^3$) | Source | Background Exposure Allocation (%) | Source |
|---|---|---|---|---|---|---|
| antimony | - | - | 21 | RIVM (2008). Converted from TDI of 0.006 mg/kg/day. | 0% | Negligible. |
| arsenic | - | - | 1 | RIVM (2000). | 0% | ASC NEPM (2013). |
| cadmium | - | - | 0.005 | WHO (2000a). | 20% | ASC NEPM (2013). |
| chromium III | - | - | 0.1 | ATSDR (2008) | 0% | ASC NEPM (2013). Consistent with CrVI. |
| chromium VI | - | - | 0.1 | US EPA IRIS (2015). | 0% | ASC NEPM (2013). |
| lead | - | - | 0.5 | WHO (2000a). | 0% | Negligible. |
| manganese | - | - | 0.15 | WHO (2000b). | 20% | ASC NEPM (2013). |
| mercury | - | - | 0.2 | WHO (2003). | 10% | ASC NEPM (2013). |
| nickel | - | - | 0.02 | EA (2009). | 20% | ASC NEPM (2013). |
| Cyanide | - | | 0.8 | USEPA (2010). | 0% | ASC NEPM (2013). |
| dioxins and furans as PCDD and PCDF | - | - | 0.00000805 | DEH (2005). Converted NHMRC TMI (70 pg/kg body weight/month) to TDI ($2.3 \times 10^{-9}$ mg/kg/day) to RfC. | 57% | DEH (2004) |
| PAHs as benzo(a)pyrene* | 8.70E-02 | WHO (2000b). TEF (1) | - | - | - | - |
| toluene | - | - | 5000 | US EPA IRIS (2015). | 0% | Friebel & Nadebaum (2011). |
| acetone (propanone) | - | - | 30900 | ATSDR (1994). Converted from chronic MRL of 13 ppm. | 10% | Friebel & Nadebaum (2011) (b) |
| benzene | 6.00E-06 | WHO (2010). | 30 | US EPA IRIS (2015). | 20% | Friebel & Nadebaum (2011). |
| Naphthalene* | - | - | 3.7 | ATSDR (2005) | 0% | Negligible. ATSDR (2005). |

**Notes**
CSF - Cancer slope factor.
RfD - Reference dose.
TDI - Tolerable daily intake.
TMI - Tolerable monthly intake.
(a) Those compounds with inhalation unit risk (IUR) values were considered to be carcinogens as part of this assessment. It should be noted that some compounds were assessed as both a carcinogen and non-carcinogen e.g. benzene.
(b) In absence of compound-specific background exposure data, the background exposure for semi or volatile CoPC has been set at 10% in accordance with the total petroleum hydrocarbon (TPH) background exposure allocation adopted by CRC CARE (2011) during derivation of the Health Screening Levels (HSLs).

* Based on the Total PAH stack testing results collated from 2014 to 2016, the carcinogenic PAHs (Benzo(a)anthracene, Benzo(b+j)fluoranthene, Benzo(k)fluoranthene, Benzo(g,h,i)perylene, Chrysene, Dibenz(a,h)anthracene, and Indeno(1,2,3-c,d)pyrene) have been assessed as BaP, and the average percent contribution of the carcinogenic PAHs to the Total PAH is 0.67%. The remaining contribution of PAHs (99.3%) has been assessed as naphthalene. The speciated breakdowns of the Total PAH stack testing results are presented in Appendix G.

# Risk Estimate for Commercial Worker - Inhalation Pathway (Scenario 2 - Grid Max)

**Health Risk Calculations - Inhalation of Vapour - Scenario 2 Grid Max**
**Site** Regain Tomago Facility
**Address** 638 Tomago Road, Tomago
**Client** Regain Services Pty Ltd
**Scenario:** Inhalation of Vapour by Off-site Commercial Workers (Adult)

$$Exposure\ Adjusted\ Air\ Concentration\left(\frac{\mu g}{m^3}\right) = \frac{Cair\ \left(\frac{\mu g}{m^3}\right) \times ET\ \left(\frac{h}{d}\right) \times EF\ \left(\frac{d}{y}\right) \times ED(y)}{averaging\ time\ (h)}$$

| Parameter | Description and Units | Adopted Value | Notes |
|---|---|---|---|
| Cair | Chemical concentration in air (µg/m$^3$) | See model below | Grid maximum ground level concentration (GLC) |
| ET | Exposure time (hours/day) | 9 | ASC NEPM (2013) - commercial/industrial. |
| EF | Exposure frequency (days/year) | 240 | ASC NEPM (2013) - commercial/industrial. |

The remaining contribution of PAHs (99.3%) has been assessed as naphthalene. The speciated breakdowns of the Total PAH stack testing results are presented in Appendix G.

**Potential Concentration in Soils Following Dust Deposition - Scenario 2 Grid Max**

**Site** Regain Tomago Facility
**Address** 638 Tomago Road, Tomago
**Client** Regain Services Pty Ltd

***Concentration in Soils***

$$C_s = \frac{DR \times (1 - e^{-k \times t})}{d \times \rho \times k} \times 1000$$

| Parameter | Description and Units | Adopted Value | | Notes |
|---|---|---|---|---|
| $C_s$ | Concentration of CoPC in soil (mg/kg) | See below | | Calculated using above equation (Stevens, 1991). |
| DR | Particle deposition rate for accidental release (mg/m$^2$/year) | See below | | Maximum modelled deposition rate for receptors combined. |
| k | Chemical-specific soil-loss constant (1/year) = ln(2)/$T^{0.5}$ | See below | | Calculated using equation ln(2)/$T^{0.5}$. |
| $T^{0.5}$ | Chemical half-life in soil (years) | See below | | Howard et al. (1991) for PAHs (benzo(a)pyrene) and hexachlorobenzene. NHMRC (2002) for dioxins and furans (surface soil). Conservative value adopted for heavy metals in the absense of published data. |
| t | Accumulation time (years) | 25 | | Emissions may occur for the assumed lifetime of the Facility. |
| d | Soil mixing depth (m) | 0.01 | 0.15 | It is assumed that the soil where deposition occurs is not well mixed (as would be the case in a garden or cultivated bed), and hence the mixing depth for depositied soils and dusts has been taken to be 1cm. For the assessment of potential plant uptake, a soil mixing zone of 15cm has been assumed within the root zone of plants. |
| ρ | Soil bulk-density (g/m$^3$) | 1.60E+06 | | Sandy soils (representative of surface soils) typically have bulk densities between 1.3 g/cm$^3$ to 1.7 g/cm$^3$ (McKenzie et al., 2004). In general, bulk densities greater than 1.6 g/cm$^3$ tend to restrict root growth. |
| 1000 | Conversion from g to kg | - | | |

| CoPC | Deposition Rate (total) (mg/m$^2$/year) | k (1/year) | $T^{0.5}$ (years) | $C_s$ (mg/kg) - Surface Soil | $C_s$ (mg/kg) - Soil-Plant Root Zone |
|---|---|---|---|---|---|
| antimony | | Not bioaccumulative (WHO, 2003) | | | |

WHO, 2003. Antimony in Drinking Water. Background Document for Development of WHO Guidelines for Drinking Water Quality

For metals that were considered to be bioaccumulative and/or persistent, a conservative half-life value of 100 years was adopted in the absence of published data to account for the slow (or no) breakdown in the environment.

* Based on the Total PAH stack testing results collated from 2014 to 2016, the carcinogenic PAHs (Benzo(a)anthracene, Benzo(b+j)fluoranthene, Benzo(k)fluoranthene, Benzo(g,h,i)perylene, Chrysene, Dibenz(a,h)anthracene, and Indeno(1,2,3-c,d)pyrene) have been assessed as BaP, and the average percent contribution of the carcinogenic PAHs to the Total PAH is 0.67%. The remaining contribution of PAHs (99.3%) has been assessed as naphthalene. The speciated breakdowns of the Total PAH stack testing results are presented in Appendix G.

**Health Risk Calculations - Ingestion of Home-grown Produce - Scenario 2 Grid Max**

| | |
|---|---|
| **Site** | Regain Tomago Facility |
| **Address** | 638 Tomago Road, Tomago |
| **Client** | Regain Services Pty Ltd |
| **Scenario:** | Ingestion of Homegrown Produce by Off-site Residents (Adult and Child) |

***Concentration in Home-grown Produce***

*Deposited Material on Aboveground Plants*

$$C_p = \frac{DR \times F \times (1-e^{-k \times t})}{Y \times k}$$

| Parameter | Description and Units | Adopted Value | Notes |
|---|---|---|---|
| $C_p$ | Concentration of CoPC in plant (mg/kg plant - wet weight) | See below | Calculated using above equation from HHRAP (Stevens, 1991). |
| DR | Particle deposition rate for accidental release (mg/m$^2$/day) | See below | Maximum modelled deposition rate for receptors combined. |
| F | Fraction for the surface area of plant (unitless) | 0.051 | For leafy aboveground crops, the surface area fraction (or plant interception fraction - how much of the depositing material remains on the plant) is estimated to be 0.051 (Stevens, 1991). |
| k | Chemical-specific loss constant for particles on plants (1/days) = ln(2)/T$^{0.5}$ | See below | Calculated using equation ln(2)/T$^{0.5}$. |
| T$^{0.5}$ | Chemical half-life on plant (days) | 14 | Weathering of particulates on plant surfaces does occur and in the absence of measured data, it is generally assumed that organics deposited onto the outer portion of plant surfaces have a weathering half-life of 14 days (Stevens, 1991). Conservative value adopted for heavy metals in the absense of published data. |
| t | Deposition time or length of growing season (days) | 70 | The growing season for typical aboveground plants varies, however it may be up to 70 days (i.e. tomatoes), which has been used in the calculation on concentrations during normal operations. |
| Y | Crop yield (kg/m$^2$) | 2 | Given that the residential areas surrounding the Site are typically urban low-density residential properties, the types of edible plant expected to be grown on the properties include tomatoes and beans. Corn, hay and wheat are not expected to be grown for human consumption in significant quantities in the area. For typical crops grown aboveground an average crop yield of 2 kg/m$^2$ has been adopted. |

| CoPC | DR (mg/m$^2$/day) | k (1/days) | $C_p$ (mg/kg plant - wet weight) |
|---|---|---|---|
| arsenic | 5.43E-10 | 4.95E-02 | 2.71E-10 |
| cadmium | 1.51E-09 | 4.95E-02 | 7.53E-10 |
| chromium (total) | 4.98E-09 | 4.95E-02 | 2.48E-09 |
| lead | 2.85E-09 | 4.95E-02 | 1.42E-09 |
| mercury | 4.71E-10 | 4.95E-02 | 2.35E-10 |
| nickel | 1.06E-08 | 4.95E-02 | 5.29E-09 |
| dioxins and furans as PCDD and PCDF | 6.16E-15 | 4.95E-02 | 3.07E-15 |
| PAHs as benzo(a)pyrene | 2.06E-10 | 4.95E-02 | 1.03E-10 |

*Uptake of Chemicals via Roots*

$$C_{rp} = C_s \times RUF$$

| Parameter | Description and Units | Adopted Value | Notes |
|---|---|---|---|
| $C_{rp}$ | Concentration of persistent CoPC in root of plant (mg/kg plant - wet weight) | See below | Calculated using above equation (US EPA, 2005). |
| $C_s$ | Concentration of persistent CoPC in soil assuming 15 cm mixing depth within gardens (mg/kg) | See below | Refer to Dust Deposition Model. |
| RUF | Root uptake factor (unitless) | See below | RAIS (Accessed 2018). Soil to wet plant uptake factor adopted. Value for 2,3,7,8-TCDD conservatively selected for dioxins and furans. |

| CoPC | Cs (mg/kg) - Soil-Plant Root Zone | RUF (unitless) | $C_{rp}$ (mg/kg plant - wet weight) |
|---|---|---|---|
| arsenic | 5.19E-11 | 1.00E-02 | 5.19E-13 |
| cadmium | 1.44E-10 | 1.38E-01 | 1.99E-11 |
| chromium (total) | 4.76E-10 | 1.87E-03 | 8.91E-13 |
| lead | 2.73E-10 | 1.12E-02 | 3.05E-12 |
| mercury | 4.50E-11 | 2.25E-01 | 1.01E-11 |
| nickel | 1.01E-09 | 1.50E-02 | 1.52E-11 |
| dioxins and furans as PCDD and PCDF | 3.80E-16 | 8.76E-04 | 3.33E-19 |
| PAHs as benzo(a)pyrene | 1.80E-12 | 2.14E-03 | 3.85E-15 |

| | | |
|---|---|---|
| Soil bulk density ($g/cm^3$) | 1.63 | Assumed for typical soil in root zone |
| Soil-water content by volume ($cm^3/cm^3$) | 0.13 | Assumed for typical soil in root zone |
| Fraction organic carbon (foc) | 2% | ASC NEPM (2013) |
| Fraction tnat is home-grown | 10% | ASC NEPM (2013) - HIL A |

**Scenario:** Ingestion of Poultry and Eggs by Off-site Residents (Adult and Child)

***Concentration in Eggs***

$$A_{egg} = [\Sigma(F_i \times Qpi \times Pi) + Qs \times Cs \times Bs] \times (Ba_{egg})$$

| Parameter | Description and Units | Adopted Value | Notes |
|---|---|---|---|
| $A_{egg}$ | Concentration of COPC in eggs (mg COPC/kg FW tissue) | See model below | Calculated using above equation. |
| $F_i$ | Fraction of plant type (i) (grain) grown on contaminated soil and ingested by the animal (chicken) (unitless) | 1 | Recommended by HHRAP (US EPA, 2005). Assumed 100% of the plant material eaten by chickens were grown on soil contaminated by emission sources. |
| $Qp_i$ | Quantity of plant type (i) (grain) eaten by the animal (chicken) each day (kg DW plant/day) | 0.2 | Recommended by HHRAP (US EPA, 2005). Estimated for grain feed only. |
| $P_i$ | Concentration of CoPC in plant type (i) (grain) eaten by the animal (chicken) (mg/kg DW) | See home-grown produce model | Refer to $C_p$ and $C_{rp}$ (mg/kg plant - wet weight). Although $C_p$ and $C_{rp}$ are presented as a wet weight, this is unlikely to affected the outcome of the assessment as dust deposition rates included both wet and dry deposition. |
| Qs | Quantity of soil eaten by the animal (chicken) (kg/day) | 0.022 | Recommended by HHRAP (US EPA, 2005). |
| Cs | Average soil concentration over exposure duration (mg CoPC/kg soil) | See dust-deposition model | Refer to $C_s$ Soil-Plant Root Zone (mg/kg) |
| Bs | Soil bioavailability factor (unitless) | 1 | Default value recommended by HHRAP (US EPA, 2005). |
| $Ba_{egg}$ | CoPC biotransfer factor for eggs (day/kg FW tissue) | See model below | The highest biotransfer factor for eggs recommended by the HHRAP Database (US EPA, 2005) or published by OEHHA (2015) was conservatively selected in the HHRA.<br>OEHHA values were adopted for arsenic, lead, mercury, nickel and dioxins and furans (value for 2,3,7,8-TCDD adopted for dioxins and furans).<br>HHRAP Database values were adopted for chromium and PAHs. For chromium, an egg biotransfer coefficient was not available and therefore fat transfer coefficients were estimated from the beef transfer coefficient. The egg biotransfer coefficient was then estimated by using the fat transfer coefficient and assumed that eggs contain a fat content of 8% consistent with US EPA (2005) and the following equations:<br>$Ba_{beef} = 10^{logBafat} \times 0.19$<br>$Ba_{egg} = 10^{logBafat} \times 0.08$ |

| CoPC | Concentration of CoPC in Plant (mg/kg DW) ($P_i$) | Cs (mg/kg) - Soil-Plant Root Zone | $A_{egg}$ | |
|---|---|---|---|---|
| | | | CoPC biotransfer factor for eggs ($Ba_{egg}$) (day/kg FW tissue) | Concentration of COPC in eggs ($A_{egg}$) (mg COPC/kg FW tissue) |
| arsenic | 2.71E-10 | 5.19E-11 | 7.00E-02 | 3.88E-12 |
| cadmium | 7.73E-10 | 1.44E-10 | 1.00E-02 | 1.58E-12 |
| chromium (total) | 2.49E-09 | 4.76E-10 | 2.32E-03 | 1.18E-12 |
| lead | 1.43E-09 | 2.73E-10 | 4.00E-02 | 1.16E-11 |
| mercury | 2.45E-10 | 4.50E-11 | 8.00E-01 | 4.00E-11 |
| nickel | 5.30E-09 | 1.01E-09 | 2.00E-02 | 2.17E-11 |
| dioxins and furans as PCDD and PCDF | 3.07E-15 | 3.80E-16 | 1.00E+01 | 6.23E-15 |
| PAHs as benzo(a)pyrene | 1.03E-10 | 1.80E-12 | 1.58E+00 | 3.26E-11 |

***Ingestion of Eggs***

$$Intake\ Factor = \frac{IR \times FI \times ME \times EF \times ED}{BW \times AT}$$

$$Daily\ Intake = Aegg \times Intake\ Factor$$

**Site** Regain Tomago Facility
**Address** 638 Tomago Road, Tomago
**Client** Regain Services Pty Ltd
**Scenario:** Ingestion of Breastmilk by Off-site Residents (Child)

***Concentration in Breastmilk***

$$C_{milk\ fat} = \frac{m \times h \times f_1}{0.693 \times f_2}$$

| Parameter | Description and Units | Adopted Value | Notes |
|---|---|---|---|
| $C_{milk\ fat}$ | Concentration of CoPC in milk fat (mg/kg) | See model below | - |
| m | Average maternal intake (mg/kg/day) | See model below | The potential maternal intake is a highly variable parameter in the above equation. It can be assumed that the calculations undertaken to calculate adult intake of each CoPC via inhalation and ingestion are relevant for a mother who may be breastfeeding an infant. |
| h | Half-life of chemical in body, adults (days) | See model below | Value from NHMRC (2002) for dioxins and furans. Value from HSDB online database for PAHs (current to 2010). Value from WHO (2011), NHMRC (2016) or the HSDB online database for most metals. For mercury, the biological half-life is stated to be 'many years', which was assumed to be 10 years. |
| $f_1$ | Fraction of ingested chemical stored in fat (unitless) | 0.9 | No data is available that is specific to the fraction of organic chemicals that may be stored as fat and hence available data for dioxins has been adopted. The fraction of ingested organic chemicals which is stored as fat is recommended to be 0.9 (US EPA, 1998). |
| $f_2$ | Fraction of mothers weight that is fat (unitless) | 0.35 | The recommended fraction of mother's body weight which is fat is 0.35 (for females in south-eastern urban areas of Australia aged 31 to 45 years (DEH, 2005)). |

| CoPC | Adult intake from air, soil (ingestion and dermal contact), home-grown, produce, eggs and beef (m) (mg/kg/day) | Half-life of chemical in body, adults (h) (days) | Concentration of CoPC in milk fat ($C_{milk\ fat}$) (mg/kg) |
|---|---|---|---|
| arsenic | 1.92E-07 | 60 | 4.27E-05 |
| cadmium | 5.33E-07 | 5475 | 1.08E-02 |
| chromium (total) | 1.76E-06 | 83.4 | 5.43E-04 |
| lead | 1.01E-06 | 10950 | 4.09E-02 |

| nickel | 3.74E-06 | 1.8 | 2.50E-05 |
| dioxins and furans as PCDD and PCDF | 2.17E-12 | 2555 | 2.06E-08 |
| PAHs as benzo(a)pyrene | 3.02E-08 | 5.5 | 6.17E-07 |

***Daily Intake from Air***

$$Intake\ Factor = \frac{InhR \times ET \times FI \times EF \times ED}{BW \times AT}$$

| Parameter | Description and Units | Adopted Value (Adult) | Notes |
|---|---|---|---|
| Intake Factor | Intake factor ($m^3$/kg/day) | See model below | - |
| InhR | Inhalation Rate ($m^3$/hour) | 1.34 | Inhalation rate assuming 20 hours indoors at 1.17 $m^3$/hour and 4 hours outdoors at 2.2 $m^3$/hour. |
| ET | Exposure time (hours/day) | 24 | ASC NEPM (2013) - low to medium density residential. |
| FI | Fraction inhaled from contamination source (unitless) | 1 | Assumed intake from contamination source for the whole ET. |
| EF | Exposure frequency (days/year) | 365 | ASC NEPM (2013) - low to medium density residential |
| ED | Exposure duration (years) | 29 | ASC NEPM (2013) - low to medium density residential |
| BW | Body weight (kg) | 70 | ASC NEPM (2013) - low to medium density residential |
| AT | Averaging time - Non-threshold (days) | 25550 | ASC NEPM (2013) - low to medium density residential |
| | Averaging time -Threshold (days) | 10585 | ASC NEPM (2013) - low to medium density residential |

| CoPC | Grid Maximum GLC (mg/$m^3$) | Non-Threshold Slope Factor (mg/kg/day)$^{-1}$ (a) | Background Adjusted Oral Reference Dose (RfD) mg/kg/day (b) | Adult Intake Factor ($m^3$/kg/day) | | Daily Intake from Air (mg/kg/day) |
|---|---|---|---|---|---|---|
| | | | | Non-Threshold Compounds (Carcinogens) | Threshold Compounds (Non-carcinogens) | |
| arsenic | 4.17E-07 | - | 1.00E-03 | 0.19 | 0.46 | 1.92E-07 |
| cadmium | 1.16E-06 | - | 3.20E-04 | | | 5.33E-07 |

## Equations

# Risk Assessment Equations

## 1.1 Estimate of Concentration in Media

**Concentration in Soil following Dust Deposition (Stevens, 1991)**

$$C_s = \frac{DR * (1 - e^{-k*t})}{d * p * k} * 1000$$

Where:

$C_s$ = Concentration of CoPC in soil (mg/kg)

DR = Particle deposition rate for accidental release (mg/m$^2$/year)

K = Chemical-specific soil-loss constant (1/year) = In(2)/T$^{0.5}$

T0.5 = Chemical half-life in soil (years)

T = Accumulation time (years)

D = Soil mixing depth (m)

P = Soil bulk-density (g/m$^3$)

1000 = Conversion from g to kg

**Concentration in Home-grown Produce**

*Deposited Material on Aboveground Plants* (Stevens, 1991)

$$C_p = \frac{DR * F * (1 - e^{-k*t})}{Y * k}$$

Where:

$C_p$ = Concentration of CoPC in plant (mg/kg plant - wet weight)

DR = Particle deposition rate for accidental release (mg/m$^2$/day)

F = Fraction for the surface area of plant (unitless)

k = Chemical-specific loss constant for particles on plants (1/days) = In(2)/T$^{0.5}$

T$^{0.5}$ = Chemical half-life on plant (days)

t = Deposition time or length of growing season (days)

Y = Crop yield (kg/m2)

*Uptake of Chemicals via Roots* (US EPA, 2005)

$$C_{rp} = C_s * RUF$$

Where:

$C_{rp}$ = Concentration of persistent CoPC in root of plant (mg/kg plant - wet weight)

$C_s$ = Concentration of persistent CoPC in soil assuming 15 cm mixing depth within gardens (mg/kg)

RUF = Root uptake factor (unitless)

**Concentration in Eggs (US EPA, 2005)**

$$A_{egg} = \left[\sum \left(Fi * Qpi * Pi\right) + Qs * Cs * Bs\right] * \left(Ba_{egg}\right)$$

Where:

$A_{egg}$ = Concentration of COPC in eggs (mg COPC/kg FW tissue)

Fi = Fraction of plant type (i) (grain) grown on contaminated soil and ingested by the animal (chicken) (unitless)

Qpi = Quantity of plant type (i) (grain) eaten by the animal (chicken) each day (kg DW plant/day)

Pi = Concentration of CoPC in plant type (i) (grain) eaten by the animal (chicken) (mg/kg DW)

Qs = Quantity of soil eaten by the animal (chicken) (kg/day)

Cs = Average soil concentration over exposure duration (mg CoPC/kg soil)

Bs = Soil bioavailability factor (unitless)

$Ba_{egg}$= CoPC biotransfer factor for eggs (day/kg FW tissue)

**Concentration in Breast Milk (US EPA, 2005)**

$$C_{milkfat} = \frac{m * h * f_1}{0.693 * f_2}$$

Where:

$C_{milk\ fat}$ = Concentration of CoPC in milk fat (mg/kg)

m = Average maternal intake (mg/kg/day)

h = Half-life of chemical in body, adults (days)

$f_1$ = Fraction of ingested chemical stored in fat (unitless)

$f_2$ = Fraction of mothers weight that is fat (unitless)

## 1.2 Estimate of Exposure

**Incidental Ingestion of Soil**

$$CDI_{ing,s} = \frac{C_s * IngR_s * EF * ED * CF}{365 \frac{days}{year} * AT * BW}$$

Where:

$CDI_{ing,s}$ = Chronic Daily Intake for Soil Ingestion (mg/kg/day)

$C_s$ = Chemical Concentration in Soil (mg/kg)

$IngR_s$ = Soil Ingestion Rate (mg/day)

EF = Exposure Frequency (days/year)

ED = Exposure Duration (years)

CF = Unit conversion factor (kg/$10^6$ mg)

AT = Averaging Time (years)

= 70 years for non-threshold carcinogens

= ED for chemicals assessed based on threshold effects

BW = Body weight (kg)

**Dermal Contact with Soil**

$$CDI_{der,s} = \frac{C_s * AH * SA * AF * EF * ED * CF}{365 \frac{days}{year} * AT * BW}$$

Where:

$CDI_{der,s}$ = Chronic Daily Intake for Dermal Contact with Soil (mg/kg/day)

AH = Soil Adherence Factor ($mg/cm^2/day$)

SA = Skin Surface Avalable for Contact ($cm^2$)

AF = Dermal Absorption Factor (chemical-specific; unitless)

and other factors are as defined earlier.

**Inhalation of Particulates or Vapours**

The following equation has been adopted to estimate intakes associated with inhalation of chemicals in air (particulates or vapours). Inhalation exposures have been estimated using the revised methodology recently published by the USEPA (USEPA, 2009), which recommends adjustment of the measured or estimated contaminant concentration in air to account for site-specific exposure considerations, rather than estimation of a chronic daily intake of contaminant via the inhalation pathway.

For particulates, it is assumed that all particulates inhaled are small enough to penetrate deep into the lungs (i.e., are inspirable), and that the particulate air EPCs have been estimated as inspirable ($PM_{10}$) dust concentrations.

$$EC_{inh} = \frac{C_a * ET * EF * ED}{AT * 365 \frac{days}{year} * 24 \frac{hours}{day}}$$

Where:

$EC_{inh}$ = Exposure Adjusted Air Concentration ($mg/m^3$)

$C_a$ = Chemical Concentration in Air ($mg/m^3$)

ET = Exposure Time (hours/day)

and other factors are as defined earlier.

**Vegetable Ingestion**

The following equation has been adopted to estimate intakes associated with the consumption of vegetables grown in soil.

$$\text{Intake Factor} = \frac{IR * FI * ME * EF * ED}{BW * AT}$$

Where:

Intake Factor = Intake factor (kg/kg/day)

IR = Ingestion rate (kg/day)

FI = Fraction ingested from a home-grown source (FI)

ME = Matrix Effect (unitless)

EF = Exposure frequency (days/year)

ED = Exposure duration (years)

BW = Body weight (kg)

AT = Averaging Time (days)

= 70 years for non-threshold carcinogens

= ED for chemicals assessed based on threshold effects

$$\text{Daily Intake} = \text{Concentration in Produce} * \text{Intake Factor}$$

**Egg Ingestion**

$$\text{Intake Factor} = \frac{IR * FI * ME * EF * ED}{BW * AT}$$

Where:

Intake Factor = Intake factor (kg/kg/day)

IR = Ingestion rate (kg/day)

FI = Fraction ingested from a home-grown source (FI)

ME = Matrix Effect (unitless)

EF = Exposure frequency (days/year)

ED = Exposure duration (years)

BW = Body weight (kg)

AT = Averaging Time (days)

= 70 years for non-threshold carcinogens

= ED for chemicals assessed based on threshold effects

$$\text{Daily Intake} = A_{egg} * \text{Intake Factor}$$

**Beef Ingestion**

$$\text{Intake Factor} = \frac{IR * FI * ME * EF * ED}{BW * AT}$$

Where:

Intake Factor = Intake factor (kg/kg/day)

IR = Ingestion rate (kg/day)

FI = Fraction ingested from a home-grown source (FI)

ME = Matrix Effect (unitless)

EF = Exposure frequency (days/year)

ED = Exposure duration (years)

BW = Body weight (kg)

AT = Averaging Time (days)

= 70 years for non-threshold carcinogens

= ED for chemicals assessed based on threshold effects

$$\text{Daily Intake} = A_{beef} * \text{Intake Factor}$$

**Breastmilk Ingestion by Infants**

$$\text{Intake Factor} = \frac{IR * FM * Ab * EF * ED}{BW * AT}$$

Where:

Intake Factor = Intake factor (kg/kg/day)

IR = Ingestion rate (kg/day)

FM = Fraction of Fat/Lipids in Milk (unitess)

Ab = Absorption Following Ingestion (unitless)

EF = Exposure frequency (days/year)

ED = Exposure duration (years)

BW = Body weight (kg)

AT = Averaging Time (days)

= 70 years for non-threshold carcinogens

= ED for chemicals assessed based on threshold effects

$$\text{Daily Intake} = C_{\text{milk fat}} * \text{Intake Factor}$$

## 1.3 Estimation of Risks

**Threshold Risk Estimates**

Risks to human health for CoPCs assessed on the basis of a threshold approach were estimated by comparison of the daily chemical intake or exposure adjusted air concentration of each CoPC with its respective TDI or Reference Concentration allowable from the Site (i.e., the TDI minus background intakes). The resulting ratio, referred to as the hazard quotient, is derived in the following manner:

$$HQ = \frac{CDI_t}{TDI - \text{background}}$$

*or*

$$HQ = \frac{EC_{inh}}{RfC - \text{background}}$$

Where:

HQ = Hazard Quotient (unitless)

$CDI_t$ = Chronic Daily Intake (calculated based on threshold averaging time) (mg/kg/day)

TDI = Tolerable Daily Intake (mg/kg/day) – adjusted for background intake

$EC_{inh}$ = Exposure adjusted air concentration ($mg/m^3$)

RfC = Tolerable Concentration in air ($mg/m^3$) – adjusted for background intake

A potentially unacceptable chemical intake/exposure is indicated if the exposure level exceeds the TDI or TC (i.e. if the hazard quotient is greater than 1).

To assess the overall potential for adverse health effects posed by exposure to multiple chemicals, the hazard quotients for each chemical and exposure pathway relevant to a receptor are summed. The resulting sum is referred to as the hazard index (HI), and is calculated using the following equation.

$$HI = \sum_{i=1,j=1}^{n} HQ_{i,j}$$

Where:

HI = Hazard Index (unitless)

$HQ_{i,j}$ = Hazard Quotient for pathway *i* and chemical *j* (unitless)

n = Number of chemicals and/or pathways relevant to land use scenario

If the HI is less than one, then cumulative exposure to the CoPC is considered unlikely to result in an adverse effect. If the sum is greater than one, a more detailed and critical evaluation of the hazards may be required, or appropriate risk management measures at the Site may need to be implemented.

**Non-Threshold (Carcinogenic) Risk Estimates**

Risks to human health for CoPC considered to be genotoxic carcinogens were estimated as the incremental probability of an individual developing cancer over a lifetime as a result of chemical exposure. The numerical estimate of incremental lifetime carcinogenic risk was calculated using the following relationship:

$$ILCR = CDI_{nt} * SF$$

*or*

$$ILCR = EC_{inh} * IUR * 10^{3} \frac{\mu g}{mg}$$

Where:

ILCR = Incremental Lifetime Cancer Risk (unitless)

$CDI_{nt}$ = Chronic Daily Intake (calculated based on non-threshold averaging time) (mg/kg/day)

SF = Cancer Slope Factor $(mg/kg/day)^{-1}$

$EC_{inh}$ = Exposure adjusted air concentration $(mg/m^3)$

IUR = Inhalation Unit Risk $(\mu g/m^3)^{-1}$

To assess the overall potential for effects posed by simultaneous exposure to more than one chemical that is associated with non-threshold carcinogenic effects, the risk for each chemical and pathway relevant to a receptor, and for adults and children (as relevant), were summed. The resulting sum is referred to as the cumulative incremental lifetime carcinogenic risk and is estimated as follows:

$$ILCR_{cum} = \sum_{i=1,j=1}^{n} ILCR_{i,j}$$

Where

$ILCR_{cum}$ = Cumulative ILCR for a given receptor (unitless)

$ILCR_{i,j}$ = ILCR for chemical i and pathway j

*n* = Number of chemicals and/or pathways relevant to land use scenario.

This approach assumes that exposure to multiple carcinogens over a lifetime results in a cumulative effect, and therefore, exposures are summed over all intake routes.

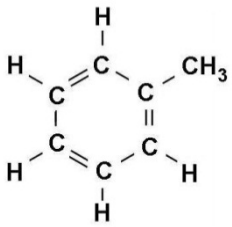
# Appendix F

## Toxicity Profiles



# Toluene – Toxicological Profile

The majority of the following information has been sourced from ATSDR (2000), with other sources listed in the references.

## Chemical Identification

Synonyms: toluene, methylbenzene

CAS: 108-88-3

Molecular Formula: $C_7H_8$

Molecular Weight: 92.142 g/mol

## General

Toluene is a clear, colourless liquid with a distinctive smell. Toluene occurs naturally in crude oil and in the tolu tree as well as being produced in the process of making gasoline and other fuels, in making coke from coal and as a by-product in the manufacture of styrene.

Toluene is used in the manufacture of paints, paint thinners, fingernail polish, lacquers, adhesives, and rubber and in some printing and leather tanning processes. It enters the environment largely as a result of solvent and petroleum spills at petrol stations on in manufacturing environments. It readily volatilizes into air and readily dissolves into groundwater and surface water bodies. Toluene is broken down by soil microorganisms and evaporates from soil and water surfaces if exposed to oxygen.

## Significance of Exposure Pathways and Background

The most likely pathway by which people may be exposed to toluene is inhalation of contaminated air and from smoking. Intake from food and water may contribute substantially smaller amounts.

CRC CARE (Friebel and Nadebaum, 2011) reviewed the air background levels in Australia for toluene and identified that background concentrations for toluene are less than 1% of the threshold toxicity criteria in the worst reported areas. It was concluded that the inclusion of background ambient air concentration does not contribute significantly to the total allowable exposure and therefore background exposure was not considered during development of the health screening levels (HSLs).

The adopted skin absorption factor was set at 12%, as adopted in CRC CARE (Friebel, E. and Nadebaum, P., 2011).

## Non-Carcinogenic Health Effects

Adverse effects on the nervous system are the critical effects of concern from acute, intermediate, or chronic exposure to toluene. Acute exposure is associated with reversible neurological symptoms progressing from fatigue, headaches, and decreased manual dexterity to narcosis with increasing exposure levels. Reversible neurological impairment from acute exposure likely involves the direct interaction of toluene with nervous system membranes. Degenerative changes in white matter regions of the brain have been correlated with the severity of persistent neurological impairment in individuals who abused solvents and have repeatedly inhaled toluene at high exposure levels (4,000–12,000 ppm). Results from studies of groups of occupationally exposed workers suggest that chronic exposure to toluene at lower exposure levels (from about 50 to 200 ppm) can produce subtle changes in neurological functions including cognitive and neuromuscular performance, hearing, and colour discrimination. Supporting data come from studies of toluene-exposed animals showing changes in behaviour, hearing loss, and subtle changes in brain structure, electrophysiology, and levels of neurotransmitters. Case reports of birth defects in children of mothers who abused toluene during pregnancy suggest that exposure to high levels of toluene may be toxic to the developing fetus. However, results from animal studies indicate that toluene is not a teratogenic agent, but can retard fetal growth and skeletal development and adversely influence behavior of offspring at exposure levels that overwhelm maternal mechanisms protecting the developing fetus from exposure. Other adverse

health effects, including cancer or effects on reproductive performance, do not appear to be of concern for persons who may experience low exposures to toluene by living or working near hazardous waste sites containing toluene.

## Identification of Non-Carcinogenic Toxicity Reference Values

The dose-response values provide an estimate of exposure to the human population that is likely to be without an appreciable risk of deleterious effects during a lifetime. The oral exposure represents a daily value and the inhalation exposure represents continuous inhalation. These values are intended for use in risk assessments for health effects known or assumed to be produced through a nonlinear (presumed threshold) mode of action (USEPA, 2013). Available chronic dose-response values published by sources recognised and endorsed by enHealth (enHealth, 2012), NEPC (NEPC, 2013) and the USEPA and are summarised below.

### Oral

The oral dose-response value is expressed in units of mg/kg/day. This value may be termed a Reference Dose (RfD), Tolerable Daily Intake (TDI), or Minimal Risk Level for oral exposure (MRL) depending on the agency of derivation.

**Table 1 Published Threshold Dose-Response Values for Toluene - Oral**

| Agency | Oral Dose-Response Value (mg/kg/day) | Source | Target Endpoint | Test Animal | UF | Notes |
|---|---|---|---|---|---|---|
| NHMRC | 0.223 | NHMRC (2016) | Liver | Rats and Mice | 1000 | TDI. Based on NTP study, 1990. |
| WHO | 0.223 | WHO (2011) | Hepatotoxic effects | Mice | 1000 | TDI. Based on NTP study, 1990. |
| ATSDR | 0.02 | ATSDR (2000) | Neurological Effects | Mice | 1000 | MRL. Intermediate duration. Based on study by Hsieh et.al., 1990 |
| Health Canada | 0.22 | Health Canada (1991) | Liver, Kidney | Rat | 1000 | TDI. Based on NTP study, 1990. |
| RIVM | 0.223 | RIVM (2001) | Liver | Mice | 1000 | TDI. Based on NTP study, 1990. |
| IRIS | 0.8 | USEPA (2005) | Kidney | Rat | 3000 | RfD. Based on NTP study, 1990. |

ATSDR – Agency for Toxic Substances and Disease Registry
CRC CARE – Cooperative Research Centre for Contamination Assessment and Remediation of the Environment
IRIS – Integrated Risk Information System
NHMRC – National Health and Medical Research Council
RIVM – National Institute of Public Health and the Environment (Netherlands)
WHO – World Health Organisation
UF – Uncertainty Factor

### Inhalation

The inhalation dose-response value is expressed in units of mg/m$^3$. This value may be termed a Reference Concentration (RfC), Tolerable Concentration (TC), Tolerable Concentration in Air (TCA) or Minimal Risk Level for inhalation (MRL) depending on the agency of derivation.

**Table 2 Published Threshold Dose-Response Values for Toluene - Inhalation**

| Agency | Inhalation Dose-Response Value (mg/m$^3$) | Source | Target Endpoint | Test Animal | UF | Notes |
|---|---|---|---|---|---|---|
| WHO | 0.26 | WHO (2000) | Central Nervous System | Human | 300 | RfC. |
| ATSDR | 0.3 * | ATSDR (2000) | Vision Impairment | Human | 100 | MRL. Chronic duration. Based on studies by Zavalic et al., 1998. |
| Health Canada | 3.75 | Health Canada (1991) | Neurological function | Human | 10 | TC. Based on study by Andersen et al., 1983. |
| RIVM | 0.4 | RIVM (2001) | Central Nervous System | Human | 300 | TCA. Based on study by Foo et al., 1990. |
| IRIS | 5 | USEPA (2005) | Neurological | Human | 10 | RfC. Based on multiple studies (1990 – 2001). |

*Converted from 8.0ppm to mg/m$^3$ using the molecular weight of 92.14 and assuming 25ºC and 760 mm Hg

## Carcinogenicity and Genotoxicity

Human and animal studies generally do not support a concern for the carcinogenicity of toluene. The only available human epidemiological studies were negative but inconclusive due to limitations in design. The validated animal inhalation bioassays were negative; however, one available oral study showed a nondose-related increase in a variety of tumors. Thus, the data do not support a firm conclusion regarding the carcinogenicity of toluene. The IARC have not classified toluene for carcinogenic effects.

Results of *in vivo* studies of exposed humans and *in vitro* microbial assays and other *in vitro* systems generally indicate that toluene is nonmutagenic and nongenotoxic.

## Adopted Dose Response Values

### Threshold (Non-Carcinogenic)

For assessment of potential threshold effects associated with oral exposure to toluene, AECOM has adopted the reference dose of **0.223 mg/kg/day** published by NHMRC (NHMRC, 2016). It should be noted that IRIS (based on an assessment undertaken in 2005) derived a slightly lower RfD of 0.08 mg/kg/day based on data from the same principle study as that used by WHO and NHMRC (NTP, 1990). The difference in the derived values results primarily from the application of an additional three-fold safety factor by IRIS (USEPA, 2013) to account for deficiencies in the toluene database. While the USEPA evaluation is therefore slightly more conservative than the WHO (2011) and NHMRC (2016) evaluations, the difference between recommended RfDs/TDIs is not significant, and AECOM has adopted the NHMRC (2016) and WHO (2011) value in accordance with the hierarchy of toxicological information sources recommended by NEPC (2013) and enHealth (2004).

For assessment of potential threshold effects associated with inhalation exposure to toluene, AECOM has adopted the inhalation reference concentration of **5 mg/m$^3$** published by IRIS (USEPA, 2013). This value was derived in 2005 based on a more comprehensive and recent review of available published toxicity studies than those undertaken by WHO (2000) and ATSDR (2000), and is therefore considered to be more suitable for quantitative dose-response assessment than the older WHO and ATSDR values.

# Naphthalene

The majority of the following information has been sourced from ATSDR (2005), with other sources listed in the references.

## Chemical Identification

Synonyms: White tar, mothballs, naphthalin, moth flakes, camphor tar, tar camphor, naphthaline, antimite, albocarbon

CAS: 91-20-3

Molecular Formula: $C_{10}H_8$

Molecular Weight: 128.18 g/mol

## General

Naphthalene occurs naturally in fossil fuels such as petroleum and coal, and is produced when organic materials (e.g., fossil fuels, wood, tobacco) are burned. Naphthalene is also produced commercially from either coal tar or petroleum. Commercially-produced naphthalene is predominately used in the production of phthalic anhydride, which is used as an intermediate for polyvinyl chloride plasticizers such as di(2-ethylhexyl) phthalate. Other uses of naphthalene include production of naphthalene sulfonates (used in concrete additives and synthetic tanning agents), pesticides (e.g., carbaryl insecticides and moth repellents), and dye intermediates.

Naphthalene is frequently present in industrial and automobile emissions and effluents and in various media in the general environment due to its natural occurrence in coal and petroleum products and emissions, its use as an intermediate in the production of plasticizers, resins, and insecticides, and its use in a variety of consumer products such as moth repellants.

## Significance of Exposure Pathways and Background

The most significant exposure pathway is inhalation of contaminated air and tobacco smoke from both active and passive smoking. Although naphthalene has been detected in certain foods, beverages and tap water, these do not constitute major sources of exposure for most people (ATSDR, 2005).

Typical air concentrations for naphthalene are low, 0.2 ppb or less. Studies of outdoor air reported concentrations of 0.09 ppb 1-methylnaphthalene and 0.011 ppb 2-methylnaphthalene. In homes or businesses where cigarettes are smoked, wood is burned, or moth repellents are used, the levels of naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene in the air are higher. Studies of indoor air typically report that average indoor air concentrations of these contaminants are less than 1 ppb (ATSDR, 2005).

As summarised in **Table 1** below, estimated chemical intakes from background exposure to PAHs (including naphthalene) in soil, drinking water, food and air are less than 1% of the lowest TDI adopted in this assessment. Background exposure was therefore not considered to be significant in comparison to the adopted dose-response criteria and TDIs were not corrected for background exposure.

**Table 1 Estimated Background Exposure to PAHs**

| Concentration of Intake | Estimated Intake (mg/kg/day) | Notes |
|---|---|---|
| **Drinking Water** | | |
| 623 ng/L | $1.78 \times 10^{-5}$ | Water concentration is the maximum reported individual PAH concentration for a range of drinking water sources monitored in the USA, United Kingdom and Europe (ATSDR, 1995). Use of this value is considered conservative given that PAHs have not been reported in Australian drinking water supplies (NHMRC, 2011).<br>Intake has been estimated for a 70 kg adult, assuming that 2 L of water per day is ingested. |
| **Food** | | |
| 10 µg/day | $1.4 \times 10^{-4}$ | Food intake is the maximum reported for individual PAHs based on a range of studies in the USA, United Kingdom and Europe (ATSDR, 1995).<br>Intake has been calculated assuming a 70 kg body weight. |
| **Air** | | |
| 10.9 ng/$m^3$ | $3.1 \times 10^{-5}$ | Air concentration is maximum annual average of any individual PAH reported in Australian cities by Environmental Australia (DEH, 1999).<br>Intake has been calculated assuming a 70 kg adult respires 20 $m^3$ of air per day. |
| | | |
| **Total Intake** | | 0.00019 mg/kg/day |
| **Minimum TDI[1]** | | 0.02 mg/kg/day |
| **Fraction of TDI Due to Background Exposure** | | 0.0096 (<1%) |

Notes
[1]Value is minimum TDI of those adopted for PAHs assessed on the basis of threshold dose-response criteria. TDIs ranged from 0.02 mg/kg/day (naphthalene) to 0.3 mg/kg/day (anthracene).

It is noted that the PAH background exposure analysis presented in this report has not explicitly considered background exposure to PAH by smokers. However, ATSDR (1995) report that concentrations of individual PAHs in cigarette smoke range from less than 1 µg per 100 cigarettes to 62 µg per 100 cigarettes. For a 70 kg individual who smokes one pack (20 cigarettes) per day, the maximum expected intake of any individual PAH is therefore estimated to be 0.00018 mg/kg/day. This additional intake due to smoking also represents less than 1% of the lowest PAH TDI considered in this assessment (0.02 mg/kg/day for naphthalene).

Background exposure is not considered in the assessment of carcinogenic (non-threshold) risks, as non-threshold risks are estimated *incremental* lifetime cancer risks. However, it should be noted that the maximum background intake estimated for individual PAHs, if assumed to apply to benzo(a)pyrene or benzo(a)pyrene toxic equivalents, would result in an estimated incremental lifetime cancer risk of approximately 9 in 100,000, which is greater than the acceptable incremental cancer risk of 1 in 100,000 adopted for this assessment . However, this cancer risk estimate should not be interpreted as an indication that exposure to background levels of PAH may cause a significant increase in cancer rates above baseline levels as the baseline lifetime risk of cancer is reported to be approximately 50% (one in two; NRC, 2006). Thus the adopted acceptable incremental cancer risk of 1 in 100,000 and the estimated cancer risk due to background concentrations of PAHs in the environment are still very low in comparison to baseline lifetime cancer risks for the population as a whole.

## Non-Carcinogenic Health Effects

Reports that establish associations between naphthalene exposure and health effects in humans are restricted to numerous reports of hemolytic anemia or cataracts following acute exposure or occupational exposure to naphthalene, either by ingestion or by inhalation of naphthalene vapours, but these reports have not identified exposure levels associated with these effects. A relationship appears to exist between an inherited deficiency in the enzyme, glucose 6-phosphate dehydrogenase (G6PD), and susceptibility to naphthalene-induced hemolysis. Newborn infants also appear to be susceptible to naphthalene-induced hemolysis presumably due to a decreased ability to conjugate and excrete naphthalene metabolites.

Results from animal studies exposed to naphthalene by oral administration, by inhalation exposure, or by parenteral administration identify several health effects of potential concern for humans, including maternal toxicity during pregnancy with acute oral exposure, decreased body weight (without lesions developing in any tissues or organs) with intermediate oral exposure, and increased incidence of non-neoplastic and neoplastic lesions in the nose (in rats and mice) and the lung (in mice only) with chronic inhalation exposure.

## Identification of Non-Carcinogenic Toxicity Reference Values

The dose-response values provide an estimate of exposure to the human population that is likely to be without an appreciable risk of deleterious effects during a lifetime. The oral exposure represents a daily value and the inhalation exposure represents continuous inhalation. These values are intended for use in risk assessments for health effects known or assumed to be produced through a nonlinear (presumed threshold) mode of action (USEPA, 2012). Available chronic dose-response values published by sources recognised and endorsed by enHealth (enHealth, 2012), NEPC (NEPC, 1999) and the USEPA and are summarised below.

### Oral

The oral dose-response value is expressed in units of mg/kg/day. This value may be termed a Reference Dose (RfD), Tolerable Daily Intake (TDI), or Minimal Risk Level for oral exposure (MRL) depending on the agency of derivation.

**Table 1 Published Threshold Dose-Response Values for Naphthalene - Oral**

| Source | Oral Dose-Response Value (mg/kg/day) | Target Endpoint | Test Animal | UF | Notes |
|---|---|---|---|---|---|

## Inhalation

The inhalation dose-response value is expressed in units of mg/m$^3$. This value may be termed a Reference Concentration (RfC), Tolerable Concentration (TC), or Minimal Risk Level for inhalation (MRL) depending on the agency of derivation.

**Table 2 Published Threshold Dose-Response Values for Naphthalene - Inhalation**

| Source | Inhalation Dose-Response Value (mg/m$^3$) | Target Endpoint | Test Animal | UF | Notes |
|---|---|---|---|---|---|
| ATSDR (2005) | 0.0037* | Nonneoplastic lesions in nasal olfactory epithelium | Rats and mice | 300 | Chronic MRL. Based on study by NTP, 1992; NTP, 2000 and Abdo et al., 2001. |
| USEPA (1998) | 0.003 | Nasal effects | Mice | 3000 | RfC. Based on Study by NTP, 1991 |
| WHO (2010) | 0.01 | Hyperplasia in respiratory epithelium and metaplasia in olfactory epithelium | Rats | 1000 | RfC. Twenty-three key studies were referenced as providing main and supporting evidence for the RfC derivation by WHO in 2010. The studies included additional chronic and subchronic inhalation studies in another animal species as well as human in vitro studies. The following three source of exposure effect evidence studies were referenced: North DW et al, 2008; Abdo KM et al, 2001 and Long PH et al, 2003, in which Nasal inflammation and olfactory epithelial metaplasia in nearly all rats chronically exposed to 53 mg/m$^3$ was considered as the LOAEL, even though related to severe effects. This was adjusted for continuous exposure (dividing by a factor of 24/6 and 7/5). Further a factor of 10 for using a LOAEL instead of a NOAEL, a factor of 10 for interspecies variation and a factor of 10 for inter-individual variation were incorporated. |

ATSDR – Agency for Toxic Substances and Disease Registry

IRIS – USEPA Integrated Risk Information System.

WHO – World Health Organization.

*Converted from 0.0007 ppm to mg/m$^3$ using the molecular weight of 128.18g/mol and assuming 25ºC and 760 mm Hg

AECOM considers that the WHO 2010 guideline value of 0.01 mg/m$^3$ for naphthalene is more appropriate for use than the USEPA 1998 RfC value of 0.003 mg/m$^3$ that was adopted by Friebel and Nadebaum (2011) in the derivation of the National Health Screening Levels (HSLs).

It is noted that the key studies which USEPA and WHO used to derive their respective inhalation TRV are very similar. The USEPA 1998 value of 0.003 mg/m$^3$ is based on study using mice exposed by

inhalation to naphthalene for 6 hours/day, 5 days/week for 2 years. Whereas the WHO guideline value is based on a study using rats, using the same exposure time (6 hours/day, 5 days/week for 2 years), and same endpoints (hyperplasia in respiratory epithelium and metaplasia in olfactory epithelium). Both studies produced a LOAEL of 53 mg/$m^3$ and adjusted for Human Equivalent Concentration (HEC), with both assessments resulting in a LOAEL HEC of 9.3 mg/$m^3$.

The only difference in the inhalation TRV determinations is an additional uncertainty factor of 3 that the USEPA used in 1998 to account for database deficiencies (10 to extrapolate from mice to humans; 10 to protect sensitive humans; 10 to extrapolate from a LOAEL to a NOAEL; and 3 for database deficiencies).

Specifically, the 1998 USEPA toxicological review indicated that the inhalation studies at that time were restricted to only the following three studies of mice:

1. A two year study (NTP 1992. Toxicology and carcinogenesis studies of naphthalene (CAS no 91-20-3) in B6C3F1 mice (inhalation studies). US Department of Health and Human Services, National Institutes of Health, Rockville, MD. Technical report series no. 410. NIH pub no. 92-3141)
2. A six month study (Adkins et al., 1986, Oncogenic response of strain A/J mice to inhaled chemicals. J Toxicol Environ Health 17:311-322); and
3. A four hour study (Buckpitt, 1982, Comparative biochemistry and metabolism. Part II: naphthalene lung toxicity. Prepared for Air Force Aerospace Medical Research Laboratory, Wright Patterson Air Force Base, OH. AFAMRL-TR-82-52, pp. 25-30).

As such, the 'lack of additional studies' contributed to the application of an uncertainty factor of 3 for database deficiencies. The toxicological database in 1998 was given a low to medium confidence rating by the USEPA because there were no chronic or subchronic inhalation studies in other animal species, and there were no reproductive or developmental studies for inhalation exposure.

In contrast, the following twenty-three key studies were referenced as providing main and supporting evidence for the guideline value derived by WHO in 2010. The studies included additional chronic and subchronic inhalation studies in another animal species as well as human in vitro studies.

Source of exposure-effect evidence (Nasal inflammation and olfactory epithelial metaplasia in nearly all rats chronically exposed to 53 mg/$m^3$ was considered as the lowest observed adverse effect level (LOAEL), even though related to severe effects).

Based on the significant increase in toxicological information for naphthalene by 2010 (when compared to the 1998 database of only three inhalation studies), a database uncertainty factor was not considered by WHO (2010) to be necessary in the derivation of their guideline. The USEPA (1998) RfC value is therefore considered to be overly conservative as it includes the database uncertainty factor of 3.

In addition, the 1998 USEPA toxicological review indicated that the results of the National Toxicity Program (NTP) inhalation cancer study with rats would provide significant information to the database when completed. The NTP inhalation cancer study with rats was completed in 2000, and is one of the key studies used WHO in their derivation of the guideline.

As per enHealth guidance in relation to choice of toxicological references, based on the currency and age of the toxicological data that has been referenced by WHO, preference is given towards the 2010 WHO value of 0.01 mg/m$^3$ for naphthalene over the 1998 USEPA RfC value of 0.003 mg/m$^3$.

## Carcinogenicity and Genotoxicity

The only studies of cancer in humans exposed to naphthalene are two case series reports of cancer; one report of four laryngeal cancer cases (all of whom were smokers) among workers in a naphthalene purification plant in East Germany, and another report of 23 cases of colorectal carcinoma admitted to a hospital in Nigeria. NTP, USEPA, and IARC concur that these studies provide inadequate evidence of naphthalene carcinogenicity in humans. No cohort mortality or morbidity studies or case-control studies examining possible associations between naphthalene exposure and increased risk of cancer (or other health effects) are available.

In animals, chronic inhalation studies have found increased incidences of non-neoplastic and neoplastic lesions in the nose of rats, non-neoplastic lesions in the nose of mice, and neoplastic and non-neoplastic lesions in the lungs of mice. In mice of both sexes, chronic inhalation of 10 or 30 ppm naphthalene induced inflammation of the nose and lung, metaplasia of the olfactory epithelium, and hyperplasia of the nasal respiratory epithelium. In female mice (but not male mice), exposure to 30 ppm (but not 10 ppm) increased the incidence of benign lung tumors (alveolar/bronchiolar adenomas) compared with controls. One other female mouse exposed to 30 ppm showed a malignant lung tumor (alveolar/bronchiolar carcinoma). In rats of both sexes, inhalation of 10, 30, or 60 ppm naphthalene induced non-neoplastic and neoplastic lesions only in the nasal cavity. Non-neoplastic nasal lesions included (1) hyperplasia, atrophy, chronic inflammation, and hyaline degeneration of the olfactory epithelium and (2) hyperplasia, metaplasia or degeneration of the respiratory epithelium or glands. Neoplastic lesions associated with naphthalene exposure in rats were olfactory epithelial neuroblastoma (a rare malignant tumor) and respiratory epithelial adenoma.

The mechanisms by which naphthalene causes non-neoplastic or neoplastic lesions in the respiratory tract of rodents are incompletely understood, but are thought to involve reactive metabolites of naphthalene, including 1,2-naphthalene oxide, 1,2-naphthoquinone, 1,4-naphthoquinone, and possibly 1,2-dihydroxy-3,4-epoxy-1,2,3,4-tetrahydronaphthalene.

Comparison of species susceptibility to naphthalene-induced non-neoplastic lung damage suggests that mice are much more sensitive than rats (e.g., non-neoplastic or neoplastic lung lesions were not found in chronically exposed rats in an NTP study) and that differences in rates and stereoselectivity of naphthalene metabolism to epoxide intermediates may be involved in this species difference. Acute (4-hour) inhalation exposure of mice to naphthalene concentrations as low as 2–10 ppm induced lung injury, whereas rats exposed to naphthalene concentrations as high as 110 ppm showed no signs of lung injury. Some evidence has been reported that rates and stereoselectivity of naphthalene metabolism in primate lung tissue may be more like rats than mice. In in vitro studies with microsomes from lymphoblastoid cells, which expressed recombinant human CYP2F1, metabolism of naphthalene to epoxide intermediates was demonstrated, but the predominant enantiomeric form produced (1S,2R-oxide) was different from the form (1R,2S-oxide) produced by mouse CYP2F2. Although these observations on epoxide formation may suggest that mice may be more sensitive than humans to acute naphthalene lung toxicity from epoxide intermediates, the possible role of other potentially reactive metabolites of naphthalene (e.g., the naphthoquinone metabolites) is unknown with chronic exposure scenarios. To date, mechanistic understanding of species differences in naphthalene bioactivation in the lung is too incomplete to definitively rule out the possible human relevance of naphthalene-induced lung lesions in mice.

In contrast, the olfactory epithelium and respiratory epithelium of the nose of rats and mice do not appear to differ in sensitivity to naphthalene non-neoplastic toxicity from chronic inhalation exposure.

Non-neoplastic nasal lesions were found in nearly all exposed animals of both species at the lowest exposure level, 10 ppm, in both chronic studies. CYP monooxygenases, which might be involved in naphthalene metabolism and bioactivation, have been demonstrated to exist in nasal respiratory epithelial and olfactory epithelial tissue from rodents and humans. Studies designed to specifically characterize metabolism of naphthalene in nasal tissue, however, have not been conducted, with the exception of a single study, which examined in vitro rates of metabolism of naphthalene to naphthalene oxides in postmitochondrial supernatants from mouse, rat, and hamster olfactory tissue. Metabolic rates (units of nmol/min/mg protein) showed the following order: mouse (87.1) > rat (43.5) > hamster (3.9). This order did not correspond with species differences in sensitivity to single intraperitoneal injections of naphthalene in a companion study. The lowest dose levels producing substantial necrosis and exfoliation in olfactory epithelium were 200 mg/kg in rats and 400 mg/kg in mice and hamsters. To date, mechanistic understanding of species differences in naphthalene bioactivation in the respiratory tissues is too incomplete to definitively rule out the possible human relevance of naphthalene-induced nasal lesions in rodents (non-neoplastic lesions in rats and mice and neoplastic lesions in rats).

It is unknown whether the naphthalene-induced neoplastic lesions found in mice (lung adenomas) and rats (nose respiratory epithelial adenomas and olfactory epithelial neuroblastomas) are produced via a genotoxic mode of action or a non-genotoxic mode requiring tissue damage and regenerative responses as precursor events. Results from genotoxicity tests for naphthalene have been predominately (but not completely) negative, and the general sites of neoplastic lesions, the nose in rats and the lungs in mice, show some correspondence (but not complete) with the general sites of non-neoplastic lesions. However, mechanistic understanding of naphthalene's carcinogenic mode of action is too incomplete to rule out the possibility of a genotoxic mode of action. Key issues that remain unexplained or unstudied include:

- The possible significance of the few positive genotoxicity results that have been obtained, including: reverse mutations in Salmonella typhimurium by 1,2-naphthoquinone; in vitro formation of N-7 guanine adducts of DNA by 1,2-naphtoquinone; reverse mutations for luminescence in the marine bacteria, Vibrio fischeri, by naphthalene; induction of sister chromatid exchanges in Chinese hamster ovary cells by naphthalene and in human mononuclear leukocytes by 1,2- or 1,4-naphthoquinone; induction of chromosomal aberrations in Chinese hamster ovaries and preimplantation mouse embryos by naphthalene; induction of somatic mutations and recombination in Drosophila melanogaster by naphthalene; and weak (about 2-fold) induction of micronuclei in red blood cells from *Pleurodeles waltl* larvae by naphthalene;
- The lack of a mechanistic explanation of why nearly all rats and mice develop nasal non-neoplastic lesions following chronic exposure to naphthalene at concentrations ≥10 ppm, but only some rats develop nasal tumors;

- The lack of a mechanistic explanation of why both male and female mice exposed to naphthalene show similar incidences of chronic lung inflammation following chronic exposure to 10 or 30 ppm, but only female mice showed statistically significant increased incidence of lung tumors;
- The lack of in vivo genotoxicity assays involving target tissues of naphthalene carcinogenicity (nose and lung); and
- The lack of information on the possible threshold exposure levels for nonneoplastic nasal lesions in rats and mice at air concentrations <10 ppm.

The National Toxicology Program 11th Report on Carcinogens includes naphthalene in its list of chemicals reasonably anticipated to be human carcinogen.

International Agency for Research on Cancer concluded that naphthalene is possibly carcinogenic to humans (Group 2B) based on specific evaluations that there is inadequate evidence in humans and sufficient evidence in animals for the carcinogenicity of naphthalene. IARC considered the findings for nasal tumors in male and female rats and lung tumors in female mice in the NTP bioassays as sufficient evidence, noting that both nasal tumor types (olfactory epithelial neuroblastomas and respiratory epithelial adenomas) are rare in untreated rats.

The USEPA last assessed the carcinogenicity of naphthalene before the availability of the results from the chronic rat bioassay. In the EPA (1998) Toxicological Review on Naphthalene, it was concluded that there was inadequate evidence in humans and limited evidence in animals of naphthalene carcinogenicity (increased incidence of lung tumors in female mice). Under the EPA 1986 cancer guidelines, naphthalene was assigned to Group C - possible human carcinogen. Under the EPA 1996 proposed cancer guidelines, it was judged that the human carcinogenic potential of naphthalene via the oral or inhalation routes “cannot be determined”, but it was noted that there was suggestive evidence of potential human carcinogenicity based on increased lung tumors in female mice. Currently, the EPA Integrated Risk Information System (IRIS) Office is reassessing the inhalation carcinogenicity of naphthalene.

## Identification of Carcinogenic Toxicity Reference Values

### Oral and Inhalation

ATSDR, RIVM, and USEPA have evaluated the carcinogenicity data for naphthalene. EPA classifies this compound as Group C, a possible human carcinogen, using criteria of the 1986 cancer guidelines (USEPA, 1986). Using the 1996 Proposed Guidelines for Carcinogen Risk Assessment (USEPA, 1996), the human carcinogenic potential of naphthalene via the oral or inhalation routes "cannot be determined" at this time based on human and animal data; however, there is suggestive evidence [observations of benign respiratory tumors and one carcinoma in female mice only exposed to naphthalene by inhalation (NTP, 1992)]. Additional support includes increase in respiratory tumors associated with exposure to 1-methylnaphthalene. An oral slope factor or inhalation unit risk for naphthalene was not derived because of a lack of chronic oral naphthalene studies. RIVM determined that naphthalene is not carcinogenic, and therefore, based its risk estimate on the threshold approach. ATSDR has published a Toxicological Profile for Naphthalene. Although ATSDR discusses the carcinogenicity data in its Toxicological Profiles, it does not currently assess cancer potency or perform cancer risk assessments.

## Adopted Dose-Response Values

Dose-response values for threshold and non-threshold effects associated with oral or inhalation exposure to naphthalene have not been published by Australian regulatory bodies.

### Threshold (Non-Carcinogenic)

For assessment of potential threshold effects associated with oral exposure to naphthalene, AECOM has adopted the reference dose of **0.02 mg/kg/day** published by USEPA (IRIS database).

For assessment of potential threshold effects associated with inhalation exposure to naphthalene, AECOM has adopted the inhalation reference concentration of **0.01 mg/m$^3$** published by WHO (WHO, 2010).

**Non-Threshold (Carcinogenic)**

For assessment of potential non-threshold effects associated with oral and inhalation exposure to naphthalene, no international values were available to adopt.

# background

The term "dioxins" describes a group of toxic organic chemicals that remain in the environment for a long time. These compounds can accumulate in the body fat of animals and humans and tend to remain unchanged for long periods. Several hundred of these compounds exist and are members of three closely related families:

- the polychlorinated dibenzo–p–dioxins (PCDDs)
- the polychlorinated dibenzofurans (PCDFs or furans)
- certain co–planar polychlorinated biphenyls (PCBs).

The National Dioxins Program (NDP) has focused on the 29 most toxic of these compounds which are recognised internationally as being harmful to humans and animals. To assist the reader, the term "dioxins" is used in this report to refer to the three families, but there are instances where specific mention is made to furans and PCBs.

The Australian Government established the program in 2001 to improve knowledge about dioxins in Australia. The program aims to determine levels, assess the risks to Australians and our environment, and to consider appropriate management actions.

Previously, limited Australian studies showed environmental levels were low, but a lack of information made it difficult to assess dioxin impacts on the environment and human health. The current studies are designed to fill this gap.

Starting in mid 2001, information studies were undertaken by leading Australian scientific organisations, with assistance from overseas experts, under contract to the Australian Government Department of the Environment and Heritage. The studies gathered information by measuring, emissions from sources such as bushfires, as well as dioxin levels in the environment, food and population.

The findings of these studies were used to determine the risk dioxins pose to our health and the environment.

Due to the high costs for laboratory analysis of dioxins, the number of samples collected for each study was limited and so caution is required when interpreting the findings. Nevertheless, these studies, completed in 2004, provide the largest survey of dioxin levels ever undertaken in Australia and provide information where no data was previously available. This document summarises the results of these studies and the conclusions of the risk assessments.

The findings will contribute to debate on how to deal with dioxins in Australia, as well as assisting Australia meet its obligations under the Stockholm Convention on Persistent Organic Pollutants (POPs). The Convention sets out a range of obligations for countries to reduce and, where feasible, eliminate releases of persistent organic pollutants, including emissions of by–product POPs such as dioxins.

The complete reports from the information studies and the risk assessment can be accessed on a CD–ROM attached to the inside back cover of this publication or from the Department of the Environment and Heritage website at http://www.ea.gov.au/industry/chemicals/dioxins/index.html. Hard copies of the reports are also available on request.

Note: the measured dioxin levels in this summary and the full reports use very small units such as nanograms, picograms and femtograms. Definitions of these and other technical terms are provided in the glossary on Page 16.

Note: The estimation of dioxin emissions (page 2 and 3) relies on data that is sometimes derived from laboratory studies and not actual measurements from facilities. This can create uncertainty in the figures which is reflected in the wide range of estimates. The 'best estimate' is the average between the highest and lowest emission factors. For more details, refer to Technical Report No 3 - Inventory of Dioxin emissions in Australia 2004.

# sources of dioxin emissions

## Dioxin emissions from bushfires

Dioxins are mainly unintended by–products of combustion processes. It has been estimated that 96 per cent of dioxins in the environment are from emissions to air. In 1998, an inventory of sources of dioxin emissions to air in Australia estimated that between 150–2,100 grams TEQ/year of dioxins are emitted each year. Wildfires, agricultural and prescribed fires were thought to be the major sources of these emissions.

Because no Australian data existed, the 1998 dioxins inventory used overseas studies and gave an estimate of between 72–1700 g TEQ/year from bushfires – a very wide range, reflecting the great uncertainty involved in the estimations. The bushfire study aimed to reduce this uncertainty by measuring the emissions of dioxins from fires in laboratories and from fires in several States and the Northern Territory. Emissions were analysed from smoke and samples of ash collected from 19 laboratory and 21 field burns.

The laboratory tests burned wheat straw, sorghum, sugarcane and forest litter. The study found that laboratory burns do not adequately simulate the combustion processes occurring in the field. Dioxin emissions from the laboratory tests were up to ten times higher than those from field fires but were comparable to other laboratory tests.

It is thought that the key difference between field and laboratory emissions may be the time the smoke plume remains at high temperatures. In field burns, air in the smoke plume rapidly cools to temperatures not supportive of dioxin formation. In wood combustion heaters, where the gases are confined, they remain at temperatures suitable for dioxin formation. A similar situation probably occurs during laboratory burns.

The field burns comprised 13 prescribed fuel reduction fires in south–east Queensland, central Victoria and south–west Western Australia, two sugarcane burns in Queensland, four fires in tropical savanna woodlands in the Northern Territory and two wildfires in north–east Victoria.

The dioxin levels, particularly from south–east Queensland, were consistent with other studies of prescribed fires. Total emissions of dioxins from field fires ranged from 0.1–2.9 pg TEQ/g of fuel.

Based on these levels and the total area of land burnt in each year in Australia, the total emissions of dioxins to air from bushfires are estimated to be 31–494 g TEQ/year, significantly lower than the 1998 estimate. Savanna fires in northern Australia accounted for most of these emissions.

A pump is used to collect smoke samples during a prescribed burn. Photo by C Meyer.

## Dioxin emissions from motor vehicles

Although motor vehicles are a source of dioxins, the level of their emissions remains uncertain. There are several reasons for this. Firstly, there is little data available on dioxins emissions from road traffic and tests on vehicles. Secondly, dioxin emissions can vary greatly due to factors including vehicle technology and age, fuel composition and ambient temperatures. Finally, in many cases, published information on dioxins emissions is contradictory. Determining dioxin emissions from motor vehicles must take account of these uncertainties.

For this study, motor vehicle emissions were determined using existing estimates and calculating the total emissions based on the total distance travelled by all Australian vehicles in 1998. This gave a range of 0.7–16.5 g TEQ/year or about 2 per cent of total emissions to air.

Leaded petrol vehicles accounted for 40–45 per cent of this amount, due to the presence of chlorinated and brominated fuel additives in leaded petrol. The presence of these chemicals is believed to account for the higher levels of dioxins in leaded petrol vehicles. However, the banning of leaded

# sources of dioxin emissions

petrol from January 2002 is expected to have already substantially reduced dioxins emissions.

Diesel vehicles account for 35–50 per cent of total dioxin emissions from motor vehicles, with most from diesel trucks. Despite unleaded petrol vehicles accounting for 65 per cent of total kilometres travelled, they account for only 5–20 per cent of total dioxins emissions from motor vehicles.

## Emissions from all dioxin sources

Using the findings of the NDP studies on emissions from bushfires and motor vehicles, as well as publicly available data on emissions from industries, a new inventory was prepared for 2002. This inventory included dioxin emissions to air, water and land, based on guidelines developed by the United Nations Environment Program. These guidelines identified nine major emission source categories. A summary, in decreasing order, for emissions to all media is shown in the table below.

The new inventory estimates that total emissions to air in Australia are between 160–1,788 g TEQ/year with a best estimate being 500 g. Uncontrolled combustion, which includes bushfires, waste burning and accidental fires, is estimated to contribute nearly 65 per cent of total emissions to air and over 80 per cent of total emissions to land, with most being emitted from grass fires.

Disposal and landfilling is estimated to be the largest source of dioxin emissions to water, contributing over 75 per cent of total emissions.

Prescribed burning and wildfires are likely to contribute at least 20–30 per cent of total dioxin emissions to the environment.

Dioxins from motor vehicles account for less than 2 per cent of total dioxins emissions to air.

# dioxins in our environment

Four studies were undertaken to measure the levels of dioxins in the environment (air, soils, aquatic environments and fauna). They were not designed to identify dioxin 'hotspots' such as contaminated industrial sites, but rather to get a picture of the background levels of dioxins in the Australian environment.

For the purposes of these studies, Australia was divided into three geographic regions:

- northern – Northern Territory and Queensland
- south–eastern – New South Wales, Victoria, South Australia and Tasmania
- south–western – south west Western Australia

Samples were collected from locations in each region, representing four different land–uses (agricultural, urban, industrial, and remote areas).

## Air

Air samples were collected continuously over monthly intervals from September 2002 to August 2003 to establish seasonal variations in dioxin levels, related, for example, to emissions from sources such as domestic wood heaters and bushfires.

The ten sites representing the four land–uses were:

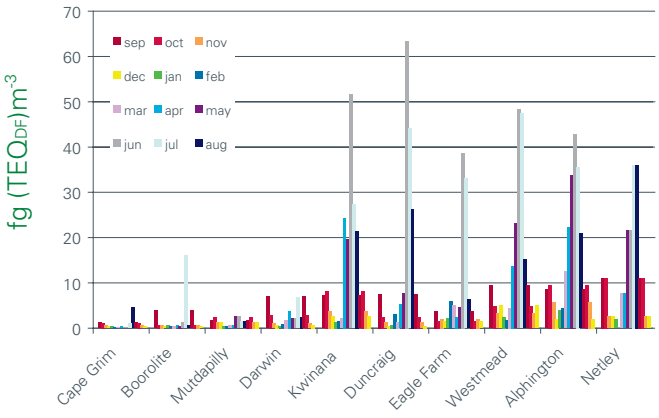
- Darwin, NT (urban)
- Eagle Farm, south–east Qld (industrial)
- Mutdapilly, south–east. Qld (agricultural)
- Westmead, Sydney, NSW (urban)
- Boorolite, lower north–east Vic agricultural)
- Alphington, Melbourne, Vic (urban)
- Cape Grim, Tas (remote – an Australian Baseline Atmospheric Pollution Station)
- Netley, Adelaide SA (industrial)
- Kwinana, Perth, WA (industrial)
- Duncraig, Perth, WA (urban)

The findings indicate an obvious seasonal cycle, with levels higher during winter in all cities, most likely due to smoke from domestic wood heaters.

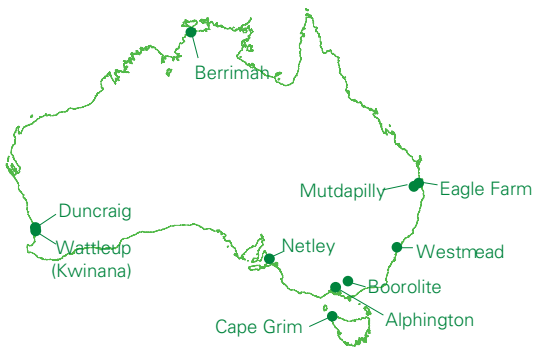
Despite the winter increase, overall mean annual levels in the major cities are still very low by world standards, with levels around 14–17 fg TEQ/$m^3$ compared with northern hemisphere cities with ranges of 20 to several hundred fg TEQ/$m^3$.

Seasonal cycles were also observed in rural Queensland and Victoria, although the cycles were weaker than in the cities.

Dioxins and furans increase over the winter months in the cities



Location of air sampling sites



# dioxins in our environment

A dry to wet season difference was observed in Darwin with levels in the dry season around six times higher than the wet season. Nevertheless, mean annual levels in Darwin are still very low (less than 4 fg TEQ/$m^3$).

Extremely low levels were observed in clean marine air at Cape Grim and in agricultural locations (typically less than 1.5 fg TEQ/$m^3$).

The relative contributions of dioxins, furans and PCBs vary across locations. The Netley site in SA has higher levels of dioxin–like PCBs compared with other sites, but these are still very low compared with other countries. Further testing is currently being undertaken to determine the source of these PCBs.

## Soils

Soils samples were collected from 86 locations across three regions and from remote sites in central and north–west Australia. Agricultural land–uses were classified according to the main agricultural practice (grazing, cotton, vegetables, sugarcane, forestry, cereals). Ten archived soils originally collected from a location near Adelaide since the 1920s were assessed for possible changes in dioxin levels.

Dioxins were found in most soils, with levels ranging from 0.05–23 pg TEQ/g dry weight. Levels across all land–use types in the northern and south–eastern regions were similar, but the levels in the south–western region were lower. Western Australia and inland areas recorded low levels.

Dioxins in soils from urban and industrial locations were substantially higher than levels in agricultural and remote locations, with the highest levels found in soils near south–east coast population centres.

Across agricultural land–uses, dioxins levels were similar, with the exception of sugarcane districts. The higher levels are not likely to be related to sugarcane cultivation since they are the same as found in non–sugarcane growing areas throughout coastal Queensland. These dioxins may be formed through natural processes.

Archived samples contained detectable levels of dioxins, with levels in the 1925 sample greater than in the samples from the 1930s and 1940s. This may have been due to storage contamination so it is difficult to determine the causes for such variation.

Across all land–uses, dioxin levels in soils are on average much lower than those reported in many industrial countries.

Dioxin levels in agricultural and remote soils in Australia compared with other countries

# dioxins in our environment

## Aquatic environment

As dioxins are insoluble in water, the most effective way of determining levels in aquatic environments is to analyse sediments and aquatic animals. Sediment samples were collected from 58 locations in freshwater, estuarine and marine locations. Samples of bivalves, such as oysters and mussels, were also collected. Fish from local commercial fisheries were included, with an emphasis on table species.

Dioxins were found in all sediments, with levels ranging from 0.002–520 pg TEQ/g dry weight. Urban/industrial areas had significantly greater levels of dioxins than samples from remote and agricultural locations.

Highest levels were found in the lower Parramatta River (100 and 520 pg TEQ/g) and the western section of Port Jackson (78 and 130 pg TEQ/g) in Sydney. These elevated levels may be due to historical contamination from former industrial sites near Homebush Bay. These sites are under going clean–up which will continue for the next five years.

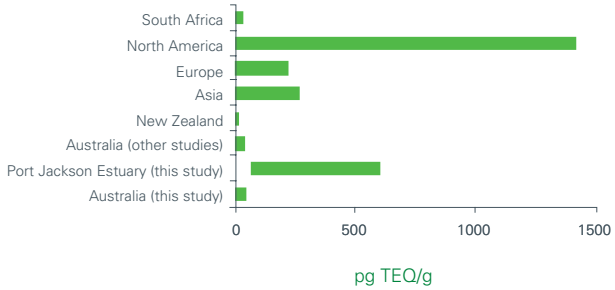
Elevated levels were found in other estuarine waters of Sydney (Botany Bay) as well as the estuaries in or near Brisbane, Melbourne, Hobart, Perth and Wollongong. Average levels across marine, freshwater and estuarine locations did not differ significantly.

The levels of dioxins in 18 bivalve samples ranged from 0.0043–0.2 pg TEQ/g wet weight, with highest levels from Port Jackson and the Yarra River, Victoria.

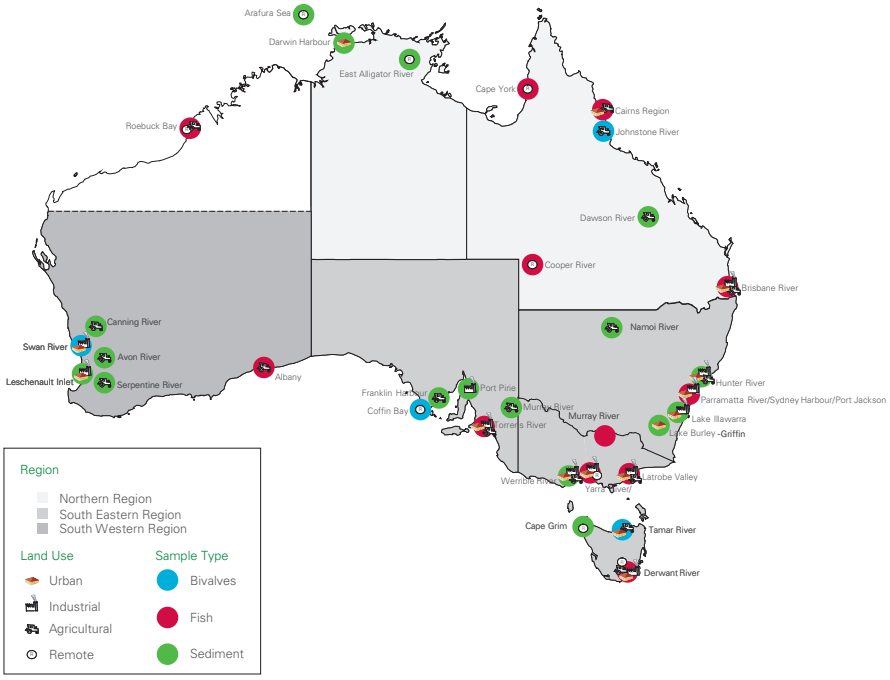
Dioxins in 23 fish samples ranged from 0.0053–0.49 pg TEQ/g wet weight. The level of dioxins was highest in fish sampled from the Sydney/Port Jackson area.

The results show dioxins levels in the aquatic environment are generally lower than for other industrialised countries but there are some sites where levels are elevated. Bivalve levels followed a similar pattern to the sediment levels. However, the fish had consistently low levels of dioxins.

### Dioxin levels in sediments in Australia compared with other countries



### Sampling locations for the aquatic study



# dioxins in our environment

## Fauna

Dioxins emitted to air can deposit on plant, soil and water surfaces. Dioxins can then enter the food chain when animals eat contaminated leaves, soils or sediments. The dioxins are then absorbed into animal fat. Dioxins increase in concentration as they move up the food chain, so that carnivores are more likely to have higher levels than herbivores.

Around 66 fauna samples were collected, mainly from dead animals, such as those near roads or stranded on beaches.

The study found the highest levels in birds of prey, with a maximum level of 3,900 pg TEQ/g lipid. Marine mammals also had comparatively high levels, with PCBs more prevalent than dioxins or furans. However, compared with other countries, the levels in marine mammals are low.

Levels were generally much lower in herbivorous animals such as kangaroos, galahs and dugongs. Levels in kangaroos ranged from 0.001–25 pg TEQ/g lipid. The levels in other marsupials (possums, koalas and bandicoots) were low and comparable to the kangaroos. Levels in platypus and echidnas ranged from 9.3–60 pg TEQ/g lipid.

Compared with fauna from other countries the levels are generally lower. The levels in birds of prey were lower than comparable species from other countries. The levels in one kangaroo sample was higher than for caribou in Canada (0.7–6.4 pg TEQ/g lipid) but less than sika deer from Japan (3.2–330 pg TEQ/g lipid). The levels in kangaroo on a fresh weight basis are even lower due to the lean nature of kangaroo meat.

For an assessment of the risk that dioxins pose to fauna, see the section What is the risk to our environment?

4. Dioxins in Ambient Air in Australia
5. Dioxins in Soils in Australia
6. Dioxins in Aquatic Environments in Australia
7. Dioxins in Fauna in Australia

Dioxin levels:
– in the environment are generally very low compared with other countries
– increase in air during winter in cities and are most likely due to emissions from domestic wood heaters
– in soils and sediments are highest in urban and industrial areas
– are higher in birds of prey than in other animals.

# dioxins in our food

## Dietary exposure

Food Standards Australia New Zealand has examined the dioxin levels in a range of foods to determine the level of dioxin exposure of Australians through food and to assess the human health risk.

Dioxin exposure through food is determined by examining dioxin levels in various foods and combining this with information on the daily diet of the population. Foods likely to contain dioxins are those that contain animal fats, such as dairy products, meat and meat products, fish and eggs.

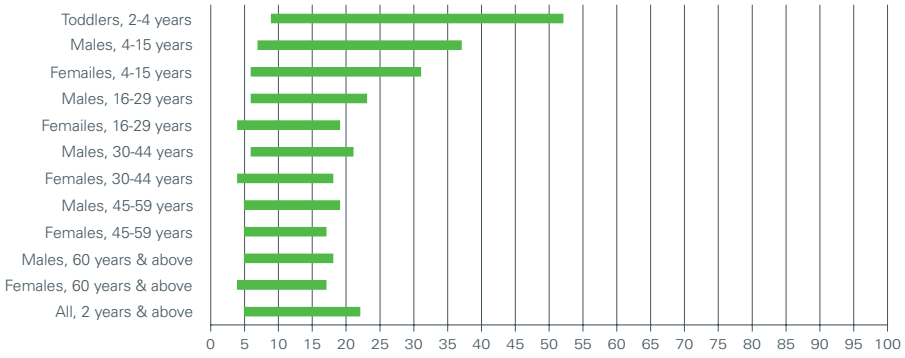
Dioxin levels in food were determined by analysis of 168 samples of 22 randomly sampled foods from Australian retail outlets which were prepared ready to eat. The mean range of dioxin concentrations found in the foods analysed are shown in the table on this page. The survey found that Australian foods have low levels of dioxins – similar to those reported in New Zealand and lower than other countries. These results were then combined with dietary information from the 1995 National Nutrition Survey to assess the population's dietary exposure.

As shown in the figure below, for all age groups from two years and over, the estimated monthly dietary levels of exposure to dioxins, for the average consumer, were well below the Australian Tolerable Monthly Intake (TMI) of 70 pg TEQ/kg body weight/month. Estimated monthly dietary exposures for high consumers were also below the TMI for all age groups.

Because of their high dietary intake relative to body weight, highest mean intakes for all age groups occur in infants and toddlers. In general terms, the estimated monthly level of exposure to dioxins for Australians (3.7–15.6 pg TEQ/kg body weight/month, lower to upper range) is similar to that of New Zealand (11.1 pg TEQ/kg body weight/month, middle value for adult males) and lower than that of other industrialised nations. For example, in the United Kingdom, the estimated exposure to dioxins for the population was 15–2pg TEQ/kg bw/month.

The major foods contributing to dioxin exposure for the Australian population over a lifetime were fish (including crustaceans and molluscs), milk and dairy products. For toddlers and children, the major foods contributing to dioxins exposure were milk and dairy products.

Mean range of exposures to dioxins for each population group in Australia, as a percentage of the Tolerable Monthly Intake.



Mean range of dioxin concentrations in food, in pg TEQ/g fresh weight

# dioxins in our food

As there are limitations associated with the data used to characterise the risk associated with exposure to dioxins from food, in general, conservative assumptions were used to minimise the possibility that risks would be underestimated. On the basis of this analysis the public health and safety risk for all Australians from exposure to dioxins from foods is very low.

## Agricultural commodities

The National Residue Survey, managed by the Australian Government Department of Agriculture, Fisheries and Forestry, collected around 220 samples of meat, fish and milk during November and December 2002.

The study found dioxin levels in these commodities are low and compare favourably with overseas products.

In the absence of an Australian commodity standard for dioxins and furans, the levels were compared against the European Union (EU) standard, as shown in the table below. None of the samples contained dioxin and furans exceeding this standard. The EU standard only refers to dioxins and furans and does not currently include dioxin–like PCBs. It is expected a new EU standard will be developed in the next few years which will include dioxin–like PCBs.

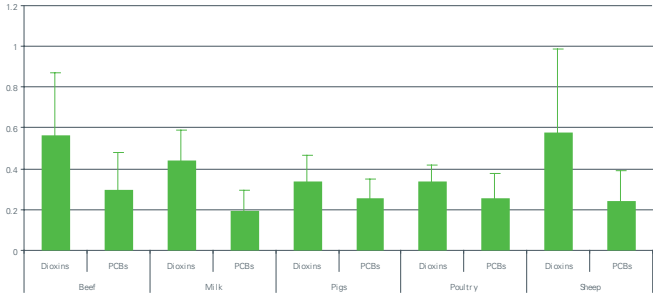
(T–lines indicate the highest level)



Species

# dioxins in our bodies

Dioxins emitted to air can deposit on plant, soil and water surfaces. Dioxins can then enter the food chain when animals eat contaminated leaves, soils and sediments. In aquatic environments, filter–feeding animals can absorb dioxins when they filter sediments in the water. The dioxins are then absorbed into animal fat. Dioxins increase in concentration as they move up the food chain.

The consumption of animal products with high fat content, such as meat and dairy products, can increase human exposure to dioxins. Dioxins accumulate in body fat and the average concentration increases with age.

To determine dioxin levels in Australians, two studies were undertaken – one assessed levels in blood serum of the whole population and the other assessed levels in the milk of first–time mothers.

## Blood serum

Blood serum samples were collected through a national pathology laboratory from over 9,000 individuals. They were pooled into 96 samples based on gender, age (under 16, 16–30, 31–45, 46–60 and over 60 years), and the following five regions:

- north–east (Brisbane, Tweed and Gold Coast and major population centres in Qld)
- south–east (Sydney, Canberra, Wollongong, Newcastle and other major population centres from NSW)
- south (Melbourne, Adelaide, Hobart and other major population centres from Victoria)
- west (Perth and other major population centres in WA)
- one rural region (all States and the NT).

The levels in the Australian population are very low by international standards, with a mean of 10.9 pg TEQ/g of lipid. They are comparable with, although lower than, those in the New Zealand population.

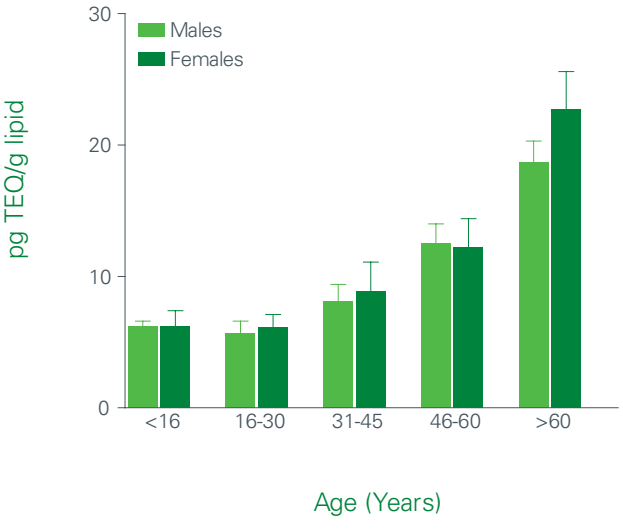
Dioxins levels between males and females showed no differences, except that slightly higher levels of dioxins were observed in females in the over 60 years age group. This result could not be explained on the basis of differences in the mean age between males and females in this group.

The study found dioxin levels increased with age. Reasons for this include on–going accumulation over a lifetime, the possibility that older people were exposed to much higher levels in the 1940s–1960s, and potential differences in metabolism and body fat.

Dioxin levels across the five regions were similar in each age range. Samples from the south–east region have slightly higher dioxin levels and females under 16 years have the highest levels of dioxins in rural regions.

As samples did not identify the donor, an assessment of any regional differences was complicated. The samples did not allow assessment of how long an individual lived in an area, their food intake or exposure to environmental contaminants.

Levels of dioxins in different age groups



# dioxins in our bodies

## Breast milk

Since breast milk is a rich source of fat, analysis of the levels of dioxins is valuable for estimating the total amount of dioxins in humans.

In order to compare the results with previous World Health Organization studies, mothers were selected using the following criteria:

- first–time mother with a baby aged two to eight weeks
- exclusively breast feeding
- willing to provide a minimum of 100 ml of milk over a six week period (two–eight weeks after birth)
- healthy pregnancy, mother and child
- a resident of the area for the past five years.

In total, 173 individual samples were collected from 12 metropolitan and rural regions (Brisbane, Sydney, Melbourne, Adelaide, Perth, Hobart, rural inland NSW, rural Queensland, rural Victoria, Newcastle, Wollongong and Darwin). These were pooled into 17 samples for dioxin analysis.

Dioxins were detected in all groups, with a mean of 9 pg TEQ/g of lipid. There were no significant differences observed in the levels collected from the different regions.

These samples were compared with samples collected from Melbourne women in 1993 and showed that levels had almost halved from 1993 to 2003.

Breast milk may contain low levels of dioxins because of its fat content, but all babies are exposed to dioxins even if they are not breastfed. Alternative foods for babies, such as infant formula, may also contain dioxins because of their fat content. Breast feeding is still the normal and most appropriate method for feeding infants, as supported by the World Health Organization.

View the full reports of the studies of dioxins in our bodies on the CD–ROM at:

9. Dioxins in the Australian Population: Levels in Blood
10. Dioxins in the Australian Population: Levels in Human Milk

Dioxin levels in our bodies
– are low by international standards and have declined, reflecting similar world–wide trend over recent decades
– increase with age.

### Levels of dioxins in the breast milk of Australian women compared with other countries

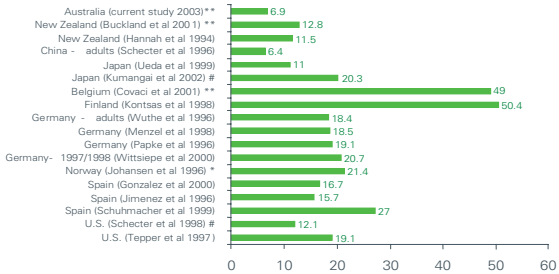
### Levels of dioxins and furans in Australians compared with other countries

Note this figure does not include PCBs



# what is the risk to our environment?

Risk assessment is the process of estimating the potential impact of chemicals or other factors on people or on the environment, under a set of conditions and for a certain timeframe. Risk assessment identifies and characterises potential hazards, and determines the likelihood of their occurrence at the known levels of exposure.

Ecological risk assessment determines if chemicals will have adverse impacts on organisms in the environment. Unlike human health risk assessment, which seeks to characterise risks to individuals, ecological risk assessments aim to characterise risks to ecosystems, populations and species.

Dioxins can adversely affect many vertebrate species. At low levels they can disrupt the development of the endocrine, reproductive, immune and nervous systems of the offspring of fish, birds and mammals.

This ecological risk assessment has three main parts: the hazard assessment, the exposure assessment, and the risk characterisation. This hazard assessment used published studies examining the toxic effects of dioxins on a limited number of species. The data from these studies were adopted to assess the potential risk to native wildlife, for which no toxicity data is available. The exposure assessment was based on the data from the soil, aquatic environment and fauna studies. The risk characterisation was performed by combining information from the hazard and exposure assessments, to estimate the likelihood of harm.

The risk assessment found that:

- Dioxins, furans and PCBs contributed equally to the load in birds and terrestrial mammals, while for marine mammals, PCBs contributed over 90 per cent of the load in dolphins and seals, and over 80 per cent in whales
- There is a potential risk to birds of prey from exposure to dioxins
- Terrestrial mammals are at a low risk when exposed to background levels of dioxins. However, the absence of data on the toxicity of dioxins to native marsupials and monotremes adds significant uncertainties to this assessment. The effect of different reproduction strategies between placental mammals and marsupials for dioxin exposure at sensitive life stages is not known
- Fish are at a low risk when exposed to the dioxin levels found in the Australian aquatic environment. This assessment is based on levels found in fish caught for the aquatic environment study
- Marine mammals living in the open oceans of Australia have no risk
- Based on the small number of samples collected in the fauna study, a potential risk is indicated for dolphins living in the vicinity of urban/industrial estuaries, which had higher levels of dioxins in their bodies than mammals living in the open ocean.

# what is the risk to our environment?

## Limitations of the assessment

All risk assessments have uncertainties due to knowledge and data gaps, which require the adoption of assumptions to cover these gaps. This assessment was no exception. The conclusions are based on the small number of fauna samples, comprising a limited number of species whose sensitivity to the toxic effects of dioxins is unknown.

A conservative approach has been adopted in this risk assessment to prevent underestimation of the risk. Inherent uncertainties should be taken into account when interpreting the results of the risk assessment.

More reliable risk estimations would require information on the toxicity of dioxins to Australian wildlife. Animal ethics committees and current State legislation generally do not allow toxicity testing on native species. More targeted sampling of birds of prey and other species, in association with field observations of potentially exposed populations, would help to clarify whether dioxins are having a real impact on bird populations.

View the full report of the ecological assessment on the CD–ROM at:
11. Ecological Risk Assessment of Dioxins in Australia

Dioxins are higher in carnivorous animals such as birds of prey and lower in herbivores such as kangaroos. There is a potential risk to marine mammals living near urban areas and to birds of prey.

# what is the risk to our health?

## Dioxins in the general population

The human health risk assessment used data from the information studies and the findings of overseas studies.

For the general population, over 95 per cent of exposure to dioxins is through the diet, with foods of animal origin such as meat, dairy products and fish being the main sources. Based on the dietary study of dioxins, the intake of dioxins for the Australian population is lower than in most other countries.

An Australian Tolerable Monthly Intake value for dioxins of 70 pg TEQ/kg body weight/month, was recommended by the National Health and Medical Research Council and the Therapeutic Goods Administration in 2002. This human health standard was based on the most sensitive reproductive effects of dioxins in animals. The risk assessment found that for Australians aged 2 years or older, the monthly intake of dioxins was between 3.9–15.8 pg TEQ/kg bw/month or between 6–23 per cent of the Tolerable Monthly Intake.

Intakes are lower in females than males for the same age, and decline with age in both sexes, the most rapid decline occurring after puberty. Infants and toddlers had a higher intake.

Using the findings of the blood serum study, body burdens and average lifetime daily exposures (ALDE) were calculated. The mean ALDE was estimated as 1.32 TEQ pg/kg bw/day (minimum of 0.13 pg/kg bw/day for ages under 16 years; maximum of 2.96 pg/kg bw/day for 60 years and older). The ALDE estimate is higher than the estimated dietary intake because it includes historical exposures, which are likely to have been higher than current exposures, as well as intake of dioxins from non–food sources.

These intake figures are not a significant cause of concern and are lower than those in other developed countries.

## Exposure to dioxins from other sources

Dioxins enter the environment mainly from combustion processes.

Intake of dioxins through the skin, ingestion from soil and from breathing are minor contributors to exposure of the general population. Cigarette smokers are likely to have higher intakes of dioxins than non–smokers.

Australia has low dioxin levels compared to other industrialised countries. It is possible that the largest emitters to the environment are not the major contributors of dioxins contamination of food. Nevertheless, protection of land and aquatic environments used for food production is important to reduce the intake of dioxins.

This assessment, whilst not an occupational health and safety risk assessment, also briefly considered 'special' populations who may have been exposed to dioxins above background levels e.g. workers who used pentachlorophenol (PCP) for treating timber and dioxin–contaminated 2,4,5–T herbicide. In view of the relatively small number of occupationally exposed cases known or studied in Australia, as well as the lack of data on blood levels of dioxins in these workers, it has not been possible to draw clear conclusions about the health effects of such exposures. PCP and 2,4,5–T were withdrawn from use in Australia a number of years ago.

# what is the risk to our health?

## Dioxins in breast milk

Unborn children are exposed to dioxins in the womb, and nursing infants are exposed to dioxins in breast milk. Because of their high dietary intake relative to bodyweight, the highest mean intake of dioxins for all age groups occurs in infants and toddlers. These findings do not change the health advice that breast milk provides the ideal nutritional start to life. The intake in question is low and gets lower as the body develops to adult size.

## Dioxins and cancer

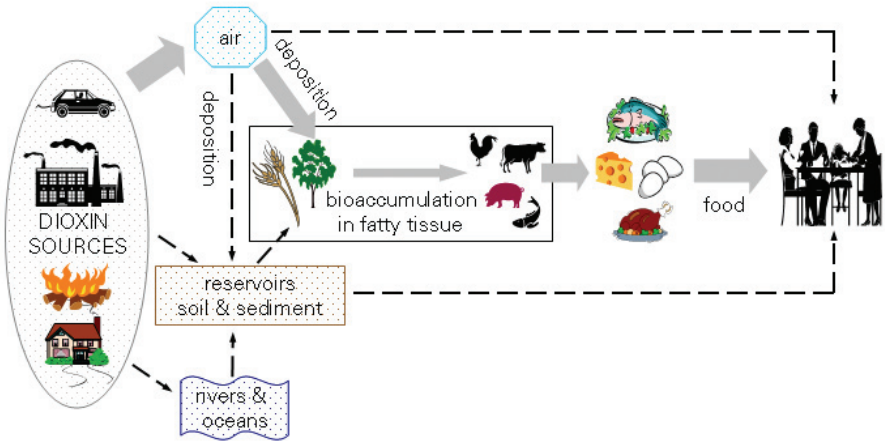
A number of agencies in other countries have tried to provide quantitative estimates of cancer risk, based on low–dose extrapolation from both animal and human data. The difficulties with estimating cancer risk include ongoing debate about the existence of a threshold level below which dioxins will not increase cancer risk and questions about the potency of the dioxins in causing cancer. Consequently, given the variability in quantitative risk estimates, this assessment has not attempted to make a quantitative risk conclusion.

The estimated intakes are below the Tolerable Monthly Intake, providing an adequate margin of safety for any possible increased risk of cancer. Furthermore, it is noted that the levels of dioxins in Australians are well below the levels associated with increased cancer risk in humans that has been seen in highly exposed industrial workers and communities exposed to industrial accidents in other countries.

View the full report of the health assessment on the CD–ROM at:
12. Human Health Risk Assessment of Dioxins in Australia

The monthly intake of dioxins from food for Australians older than 2 years was between 3.9–15.8 pg TEQ/kg bw/month or between 6–23 per cent of the Tolerable Monthly Intake. The risk to the health of Australians is very low.

Pathway for dioxins entering our bodies



# glossary

| | |
|---|---|
| Lipids | Lipids include fats and oils. |
| Limit of detection | Limit of detection, the lowest level at which a chemical can be measured in a sample by the analytical method used. |
| TEQ | Toxic Equivalents – allows the toxicity of a complex mixture to be estimated and expressed as a single number. A set of weighting factors has been determined for each type of dioxin, which expresses the toxicity of each type in terms of its equivalent mass of TCDD 2,3,7,8–Tetrachlorodibenzo–p–dioxin). Multiplication of the mass of the congener by its weighting factor (or toxic equivalency factor, TEF) yields the corresponding TCDD mass (or TEQ). The total toxicity of any mixture is the sum of the TEQs for each type of dioxin. |
| Upper bound | The maximum possible TEQ. |
| Units of measurement | |
| ng | nanogram $=10^{-9}$ gram (0.000 000 001g) |
| pg | picogram $=10^{-12}$ gram (0.000 000 000 001g) |
| fg | femtogram $=10^{-15}$ gram (0.000 000 000 000 001g) |
| Tolerable monthly intake | The amount of a substance which can be consumed over a month with no appreciable risk to health. |

# Foreword

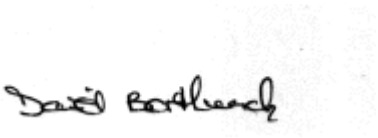
When the Australian Government established the four year National Dioxins Program in 2001, our knowledge about the incidence of dioxins in Australia was very limited.

The aim of the program was to improve this knowledge base so that governments were in a better position to consider appropriate management actions. Starting in mid 2001, a range of studies were undertaken which involved measuring emissions from sources such as bushfires, as well as dioxin levels in the environment, food and population. The findings of these studies were used to shed light on the risk dioxins pose to our health and the environment.

This work has been completed and the findings are now presented in a series of twelve technical reports.

Having good information is essential if there is to be timely and effective action by governments; these studies are a start. Our next step is to foster informed debate on how we should tackle dioxins in Australia, as this is an obligation under the Stockholm Convention on Persistent Organic Pollutants. The Department of the Environment and Heritage will be working closely with other Australian Government, State and Territory agencies to take this step.

Ultimately, the effective management of dioxins will be the shared responsibility of all government jurisdictions with the support of the community and industry.



David Borthwick
Secretary
Department of the Environment and Heritage

# Acknowledgements

The Department of the Environment and Heritage (DEH) would like to acknowledge the following individuals and organisations that contributed to the information studies and risk assessments under the National Dioxins Program:

- the project teams from the CSIRO, the National Research Centre for Environmental Toxicology and Pacific Air & Environment who undertook the studies assessing the levels of dioxins in the environment, the population and from emission sources, the overseas experts who provided advice to these organisations, and the many individuals across Australia who collected the samples in the field
- the Department of Agriculture, Fisheries and Forestry, who assessed the levels of dioxins in agricultural commodities
- Food Standards Australia New Zealand and the Department of Health and Ageing and who assessed the levels of dioxins in foods and assessed the health effects of dioxins
- officers of the Chemical Assessment Section in DEH who assessed the ecological effects of dioxins
- members of the National Dioxins Project Team which included representatives from the State and Territory environment protection agencies, the Australian Health Ministers Conference and the Primary Industries Ministers Council
- members of the National Dioxins Consultative Group which included representatives from industry and agricultural sectors, environment and public health groups and research institutions.

# Project Team

This health risk assessment was conducted by the Office of Chemical Safety (OCS) within the TGA Group of Regulators, part of the Australian Department of Health and Ageing (DoHA). Preparation of the report was coordinated by Dr Les Davies. Chapter authors were Drs Les Davies, Graham Harvey, Kaylene Raynes, Michael Dornbusch and Deborah Willcocks. Ms Joanne Cuthbert was responsible for collation and indexing of the manuscript.

In-house review and editorial comments were provided by Dr Utz Mueller and Mr Mark Jenner of the OCS and Mr Jack Dempsey of the Population Health Division of DoHA. Comments and suggestions have been received from several State and Territory Government agencies, industry and community groups. External peer reviewers were Professor Helen Hakansson, Environmental Health Risk Assessment Unit, Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden, and Steve Hrudey, Professor of Environmental Health Sciences, Department of Public Health Sciences, University of Alberta, Edmonton, Canada.

# Preface

Dioxins are a group of fat-soluble chemicals which are highly persistent in the environment and which can accumulate in the body fat of animals. If exposure to dioxins is sufficiently extensive, they can cause a range of toxic effects in animals and humans, including skin lesions, reproductive disorders and cancer.

In Australia, relevant Australian Government agencies have been undertaking monitoring programs to determine whether dioxins and related compounds are present in humans, the environment, food, and in certain agricultural commodities. As part of these monitoring programs and their reporting, the Department of Environment and Heritage (DEH) and the Department of Agriculture, Fisheries and Forestry (DAFF) sought advice from the Department of Health and Ageing (DoHA) on establishing a tolerable intake for dioxins and related compounds.

Largely based on the deliberations of (1) the consultation between technical experts representing the World Health Organization European Centre for Environmental Health (WHO-ECEH) and the International Programme on Chemical Safety (IPCS) in May 1998; (2) the meeting of the European Community Scientific Committee on Food (EC-SCF) on the risk assessment of dioxins and dioxin-like polychlorinated biphenyls (PCBs) in food, in May 2001; and (3) the Joint Food and Agriculture Organization of the United Nations (FAO)/WHO Expert Committee on Food Additives (JECFA) evaluation of dioxins, at its 57th meeting in June 2001, Australia established a Tolerable Monthly Intake (TMI) for dioxins of 70 pg TEQ/kg bodyweight from all sources combined. This tolerable intake is equal to that set by JECFA, and includes polychlorinated dioxins, polychlorinated furans and dioxin-like PCBs, as specified under the WHO 1998 TEF scheme. This TMI was endorsed by the National Health and Medical Research Council (NHMRC) on 24th October 2002, as outlined in the booklet, Dioxins: Recommendation for a Tolerable Monthly Intake for Australians, published jointly by the NHMRC and the Therapeutic Goods Administration (TGA)[1], organisations within DoHA.

The tolerable intake value is a human health standard based on the toxicological effects of dioxins and related compounds in animals and humans, following known exposures. The tolerable intake value is not a measure of human exposure to dioxins and it is not an action level for dioxins in food or the environment. Rather, it is an intake standard, against which estimated human exposure from all sources combined should be compared.

This risk assessment document has estimated exposure of the Australian population to dioxins, based on levels measured in monitoring programs conducted by the DEH (air, soil, water sediments etc.), by DAFF (agricultural commodities) and Food Standards Australia New Zealand (food). Intake estimates have been compared with the tolerable

[1] Available through Government Info Bookshops. To purchase a hard copy, please contact AusInfo on their toll-free number 132 447, or via www.ausinfo.gov.au/general/gen_hottobuy.htm. The report is accessible electronically through the NHMRC homepage at http://www.nhmrc.gov.au.

monthly intake value in order to make an assessment as to whether there are likely to be any health risks to different segments of the Australian population. Furthermore, intake estimates and body burdens of dioxin-like compounds have been compared with equivalent values estimated in other countries, to see whether the population is more or less exposed than populations in other parts of the world.

It should be noted that occupational exposures are not specifically considered in this public health risk assessment, other than the inclusion of some relatively general comments about intakes from some specific exposure sources.

# Executive Summary

This report has been prepared by the Australian Department of Health and Ageing (DoHA) as an appraisal of the health risks posed to the Australian population by polychlorinated dibenzo-p-dioxins (PCDDs), polychlorinated dibenzofurans (PCDFs) and the dioxin-like polychlorinated biphenyls (PCBs), known collectively as 'dioxins' or 'dioxin-like compounds'.

The Department of Environment and Heritage collected information on the levels of dioxin-like compounds in various environmental media in Australia, including air, soil, and sediments. It also collected data on concentrations of dioxins in the blood serum of different segments of the population. In related projects, Food Standards Australia New Zealand (FSANZ) measured the levels of these compounds in various foods and estimated dietary intakes in different population subgroups, the Australian Department of Health and Ageing (DoHA) measured dioxin-like compounds in breast milk, and the Australian Department of Agriculture, Fisheries and Forestry (DAFF) reported on levels in various agricultural commodities including meat, milk and fish. These, together with other data collected by the Department of Environment and Heritage, have been used in this population exposure assessment and health risk appraisal, conducted by the Office of Chemical Safety (OCS) within DoHA. This report also presents a summary overview of our current understanding of the health risks associated with exposure to dioxin-like compounds, and reviews health guidelines that have been established by Australia and other jurisdictions.

From a consideration of the Australian exposure data, and a review of the published scientific literature on dioxin-like compounds, the following observations and conclusions can be made.

**Overview of exposure estimates for the Australian population**

For the general population, over 95% of exposure to dioxin-like compounds is through the diet, with foods of animal origin such as meat, dairy products and fish being the main sources. Generally, Australian foods have levels of PCDD/Fs and PCBs that are similar to those reported in New Zealand and lower than those reported from other areas of the world. Thus, based on a dietary study for dioxin-like compounds conducted by FSANZ (FSANZ, 2004), the level of dietary intake of these chemicals for the Australian population appears to be lower than exposures reported for any other country where exposure studies have been undertaken. For all Australians aged 2 years or older, the mean upper bound estimated monthly intake of dioxins is 16 pg TEQ/kg bw/month, where the toxic equivalents (TEQ) are based on the toxic equivalent factors (TEFs) developed in 1997 for dioxin-like compounds by the World Health Organization (WHO) (Van den Berg et al, 1998). Monthly mean intakes per unit bodyweight are lower in females than males for the same age, and decline with age in both sexes, the most rapid decline apparently occurring after puberty. Unborn children are exposed to dioxin-like compounds *in utero*, and nursing infants are exposed to these contaminants present in breast milk. Because of their high dietary intake relative to bodyweight, highest mean intakes for all age groups occur in infants and toddlers.

Similarly, the results of the study of dioxin-like compounds present in serum (Harden et al, 2004) show that measured levels in the tissues of Australians are at the low end of the scale of levels reported internationally. The mean serum concentration across the population was determined as 11 ng WHO-TEQ/kg on a lipid-adjusted basis (range: 4.6-28 ng WHO-TEQ/kg lipid). From these serum data, body burdens and average lifetime daily exposures (ALDE) were calculated. The mean ALDE for all data was estimated as 1.32 pg WHO-TEQ/kg bw/day (minimum of 0.13 pg WH)-TEQ/kg bw/day for the population aged <16 years; maximum of 3.0 pg WHO-TEQ/kg bw/day for the population aged 60 years). The higher ALDE estimate compared to the estimated dietary intake is because the ALDE includes historical exposures, which are likely to have been higher than current exposures, as well as intakes from non-dietary exposure pathways.

A study (Müller et al, 2003a) measured concentrations of PCDD/Fs and dioxin-like PCBs in milk of Australian nursing mothers collected over late 2001 to 2003. Overall mean TEQ levels (upper bound) were 9.0 ng WHO-TEQ/kg of milk fat. The levels of dioxin-like chemicals in the breast milk of Australian women are similar across all regions of Australia but low by international standards. This reflects the conclusions about body burdens of dioxin-like compounds made from the serum level data. In Australia, concentrations of dioxin-like compounds in breast milk have fallen significantly (about 45%) within the past decade, an observation consistently noted in monitoring programs from a large number of other countries. This reflects a world-wide trend over recent decades of declining levels of dioxin-like compounds in the environment and in human tissues.

The generation of dioxins results predominantly from combustion processes and atmospheric transport represents the primary route for transport of dioxins into the environment.

Intake of dioxins by dermal absorption from, or ingestion of soil and by inhalation from air are only minor contributors to exposure of the general population to dioxins. Cigarette smokers are likely to have somewhat higher intakes of dioxins than non-smokers.

It has been estimated that bushfires may contribute at least 20-30% of the total release of dioxin-like compounds to the Australian environment. Bushfires, grass and scrub fires have been part of the Australian landscape for aeons. Thus, humans and the environment have been exposed to low levels of dioxin-like compounds and human metabolism has been coping with dioxin compounds for thousands of years.

The Australian National Pollutant Inventory (NPI) 2003 estimates the relative contribution of various sources to total dioxins emissions in Australia. Comparatively low levels of PCDD/F emissions have been reported relative to most other industrialized countries. It is possible that the sources with the largest estimated total emissions to the environment are not the major contributors of PCDD/F contamination of food (the largest contributor to intake of dioxin-like chemicals for the general population).

Nevertheless, protection of land and aquatic environments used for food production is very important, in order to reduce general population intakes of dioxin-like compounds.

Higher exposures, such as may occur in the workplace, have been restricted to smaller groups of people. Historical, occupational exposures to PCDD/Fs have largely been restricted to individuals involved in the handling and use of the pesticides such as pentachlorophenol (PCP) and 2,4,5-trichlorophenoxyacetic acid (2,4,5-T). These chemicals are no longer approved for use in Australia.

**Toxic effects of dioxin-like compounds**

The most widely studied of all the dioxin-like compounds is 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (2,3,7,8-TCDD, or TCDD). It has been shown to affect a wide range of organ systems in many animal species and can induce a wide range of adverse biological responses. The binding of TCDD to the so-called aryl hydrocarbon (*Ah*) receptor in cells appears to be the first step in a series of events that manifest themselves in biological responses, including changes at the biochemical, cellular and tissue level. Binding to the *Ah* receptor occurs in laboratory animals and humans. This being the case, the results of studies in animal have been used to predict health effects that may not yet have been demonstrated in human studies. Notwithstanding this common mechanism of action, it is noted that there are considerable species and strain differences in the acute toxicity of dioxins.

Adverse effects reported in animals following exposure to dioxins include immunotoxicity, endometriosis in Rhesus monkeys, developmental, behavioural effects in offspring of treated Rhesus monkeys, and developmental effects in rats (including reproductive toxicity in males and urogenital malformations in females).

Available epidemiological data indicate that dioxin-like compounds produce a variety of biochemical responses in humans, some of which occur at relatively low exposure levels. Induction of hepatic enzymes, changes in hormone levels and reduced glucose tolerance are examples of subtle changes that may occur at comparatively low exposures. However, these subtle effects are of unknown clinical significance, and may or may not indicate a toxic response or potential for a toxic response.

In humans, the most widely recognized and consistently observed effect following high dose exposure to TCDD is chloracne. The condition can disappear after termination of exposure or can persist for many years. Other effects on the skin include hyperpigmentation and hirsutism. TCDD can cause long-term alteration in glucose metabolism and there is some evidence of a weak correlation between the incidence of diabetes and occupational or accidental exposure to dioxins; however, background exposure to dioxins is not a significant risk factor for diabetes. Effects on the respiratory system, manifested mainly as upper respiratory tract irritation, have resulted from acute exposure to high concentrations of TCDD. Other irritant effects resulting from acute exposure include conjunctivitis with red and irritated eyes, and inflamed eyelids (blepharitis). TCDD exposure has been suggested to cause slight changes in thyroid function, but clinical illness associated with immune system disorders does not appear to have been associated with TCDD in any cohort studied. There is some suggestive

evidence of toxicity to the cardiovascular system. Some studies report that higher exposure to dioxins is associated with elevated blood lipids (hyperlipidemia) and increased frequency of ischaemic heart disease (damage due to poor blood circulation), valvular heart disease, and degeneration of the retina of the eye (retinopathy).

While dioxins can increase the incidence and severity of endometriosis in monkeys, epidemiology studies and small, hospital-based case-control studies have failed to provide compelling evidence for or against an association of environmental contaminants and endometriosis in humans. Results from human studies of developmental effects and exposure to TCDD have generally been inconclusive. Studies of the risk of spontaneous abortion involving occupational and environmental herbicide exposure have generally not found increased risks. Several studies indicate that paternal exposure to dioxins may be associated with the birth of more girls than boys; however, the median concentration of dioxin in fathers in one such study was about 20 times the estimated average concentration of TCDD currently found in human beings in industrialised countries.

The potential neurotoxicity of PCBs was first recognized when people in Japan (1968) and Taiwan (1978-1979) consumed rice oil highly contaminated with PCBs and PCDFs; offspring had poorer cognitive functioning as well as other behavioural problems. In the recent Dutch PCB/Dioxin Study, assessment of school-age children suggested that subtle cognitive and motor developmental delays arising from prenatal PCB and dioxin exposure were seen when parental and home characteristics were less optimal but such effects were not measurable in children raised in more optimal environments. A number of literature studies indicate that the beneficial effects of breast feeding on infant development far outweigh any possible negative effects arising from the somewhat higher intake of dioxins in breast-fed as cf. formula-fed infants.

Of the range of non-cancer health effects evaluated in exposed adult populations, some appear to be transient and not observed when exposure ceased, whereas other effects persist for some years. Overall, epidemiology studies on populations exposed occupationally or environmentally to TCDD have not demonstrated any significantly increased all-cause or non-cancer mortality.

Experimental studies demonstrate that TCDD is carcinogenic in all species and strains of laboratory animals tested. It has been characterised as a multi-site carcinogen. However, short-term studies have shown a lack of direct DNA-damaging effects, indicating that TCDD is not an initiator of carcinogenesis, but is a potent tumour promoter. Although the mechanisms of carcinogenicity are not fully known, the ability of TCDD to enhance proliferation and inhibit apoptotic processes in focal hepatic lesions supports an indirect mechanism of carcinogenicity. Nevertheless, in the whole-of-life rat cancer study which has driven cancer risk estimates made by a number of regulatory agencies, it should be borne in mind that there were also significant reductions in the incidence of a number of cancers including spontaneous benign tumours of the uterus, benign and malignant mammary tumours and pituitary adenocarcinomas (in female rats), and in adrenal gland phaeochromocytomas and pancreatic adenomas (in male rats). Although the mechanisms for such reductions in

tumour incidence are not well understood, reductions in body weight as a result of TCDD exposure and disruption of endocrine homeostasis are two possible explanations.

Epidemiological evidence from the most highly exposed occupational cohorts studied produces the strongest evidence in humans of an increased cancer risk from exposure to dioxins, when the data are considered for all cancers combined. There is weaker evidence of an increased cancer risk when the data for cancers at particular sites are considered. From the occupational studies, and an understanding of biological plausibility as shown by animal studies, the International Agency for Research on Cancer (IARC) has concluded that TCDD is carcinogenic to humans. It is difficult to find epidemiological data that have sufficient dose-response information to provide reliable risk estimates for cancer in exposed human populations. Modelling is complicated by uncertainties in extrapolating current body burdens of dioxins to past occupational exposure and by the choice of the dose-response model to fit the data. In specific cohorts, excess risks were observed for reproductive cancers (female breast, endometrium, male breast, testis) but, overall, the pattern is inconsistent. There is a small increase in relative risk for all cancer combined in the most highly exposed and longer-latency sub-cohorts. The possibility that this small increase in relative risk is due to confounding factors cannot be excluded.

A number of key studies documenting a variety of health effects of TCDD in laboratory animals have been used to establish human health guidelines for exposure to dioxin-like compounds. However, most data on the health effects of PCDD/Fs have been obtained using the most toxic congener, 2,3,7,8-TCDD. Despite only having limited data on the toxic effects of other dioxin-like PCDD/Fs and PCBs, it may be inferred that biochemical, cellular and tissue-level effects that are elicited by exposure to TCDD are also induced by other chemicals that have a similar structure and that bind to the *Ah* receptor. Thus there is general agreement that the use of Toxic Equivalence Factors (TEFs) to estimate the potency of dioxin-like compounds (relative to TCDD) is a useful procedure, applying the concept of additivity for the PCDDs, PCDFs and dioxin-like PCBs to provide total Toxic Equivalence Quotient (TEQ) estimates. The TEQ approach involves assessing the comparative effects of individual PCDD/F and PCB congeners on various biological end-points, and deriving TEFs based on the upper range of potency data for these effects. The concept of toxic equivalents in evaluating mixtures of PCDD/Fs and dioxin-like PCBs has been fundamental to the conduct of health risk assessments. Estimates of population exposures suggest that a significant proportion of the total intake of dioxin-like compounds (measured as TEQs) is from congeners other than 2,3,7,8-TCDD.

**Tolerable Monthly Intake**

Based on an analysis of various international hazard assessments and relevant literature published between 1999 and late 2003, it is considered that the Australian Tolerable Monthly Intake (TMI) of 70 pg/kg bw/month as recommended by the NHMRC and the TGA's Office of Chemical Safety in 2002 should be adequately protective of the general population with respect to effects of dioxin-like compounds. This value is the same as that set by the WHO/FAO Joint Expert Committee on Food Additives and Contaminants (JECFA) in 2002.

**Health Risk Assessment**

Intakes of dioxins from the various sources can be compared with the Tolerable Monthly Intake (TMI) health intake value established by the TGA and NHMRC (NHMRC/TGA, 2002). For the majority of the population, their average intake of dietary dioxins (per unit bodyweight) was significantly lower than this value, being between 10-54% of the TMI, somewhat higher in infants and toddlers, based on samples taken in 2000 and food consumption data from 1995. Estimates of intake based on serum concentrations suggests that during approximately the last 25 years the average intake was probably close to 1.3 pg WHO-TEQ/kg bw/day. On international comparisons with intakes estimated in other developed countries, these figures are not a significant cause of concern. Nevertheless, on the basis of scientific uncertainties in the establishment of the tolerable health intake value, sensible policy would dictate continuing efforts to reduce, where possible, the emissions of dioxin-like compounds to the environment.

A number of national agencies have endeavoured to provide quantitative estimates of cancer risk, based on low-dose extrapolation from both animal and human data. In view of the ongoing debate about the existence of a threshold level below which dioxins will not increase cancer risk, about the potency of the various dioxins, furans and PCBs in causing cancer, and the variability in various quantitative risk estimates, this assessment has not endeavoured to make a quantitative risk conclusion. The estimated intakes are below the TMI, which provides an adequate margin of safety for any possible increased risk of cancer. Furthermore, it is noted that the body burden of dioxins in the general population is significantly lower than the body burdens of the most highly exposed industrial cohorts where there is evidence of some increased cancer risk.

On the basis of the findings of this risk appraisal, the Australian population can be confident that current background exposures to dioxin-like compounds are generally low compared with other similar countries. Because of the ubiquitous presence of various dioxin-like compounds in human tissues, as well as in the milk of mothers worldwide, infants can be exposed to these compounds both prenatally and during breast feeding. A number of studies indicate that any neurological deficits associated with exposure to dioxins and other organochlorine contaminants appears to be associated with *in utero* exposure rather than breastfeeding. This finding adds to the reasons for taking a prudent and precautionary approach with respect to risk management steps to reduce population exposures to these chemicals. Nevertheless, all the available scientific and medical studies indicate that any subtle effects which might result from early exposure to extra dioxin-like compounds in breast milk are quickly outweighed by the multiplicity of beneficial effects from breast feeding.

This report, whilst not an occupational health and safety risk assessment, also briefly considers ‘special’ populations who may have be exposed to dioxin-like compounds above background levels eg. workers who were occupationally exposed to PCDD/F from the use of PCP in the timber industry and dioxin-contaminated 2,4,5-T in agricultural woody weed control. In view of the relatively small number of occupationally exposed cases known or studied in Australia, as well as the lack of data

on blood levels of TCDD/Fs and PCBs, it has not been possible to draw clear conclusions about health effects of such exposures.

**Recommendations relating to risk management**

Notwithstanding the observation that the Australian population is exposed to low levels of dioxins, it would be prudent, in the light of the environmental persistence and long biological half-lives for many of the congeners of these dioxin-like compounds, to take all reasonable steps to further reduce human exposure, by reducing and if possible eliminating, significant sources of PCDD/PCDF generation.

Although hundreds of epidemiology studies have looked at the human health effects of dioxin exposures, neither the full extent of dioxin contamination nor the magnitude of the associated human health risks are clearly understood (eg. Institute of Medicine; Schmidt 2004). However, in the light of increasing scientific information about the toxicity of dioxin-like compounds and data on body burdens present in the Australian population, the following recommendations with respect to reducing any potential risks to human health are made:

- A cautious and conservative approach should be adopted with respect to dioxin-like compounds. Thus, programs to reduce the release of dioxin-like compounds into the environment need to be ongoing.
- Ways to block the cycling of dioxins through the food supply need to be identified. Reducing the levels of dioxins in feed given to livestock, poultry and aquaculture fish will help to reduce the levels of dioxins in the food supply. This may be achieved by reducing the amount of animal fat used as a growth enhancer in stockfeed, and sourcing fish-based aquaculture feed (eg. pilchards, sardines) from non-polluted environments.
- Since foods high in animal fats are a source of exposure to these chemicals, current efforts to promote lower saturated fat intake in the population should continue[2].
- Current programs to discourage cigarette smoking should be maintained. In particular, any measures which reduce dioxin intake in young women are likely to help reduce their body burden of dioxins and ultimately, the amount of dioxins which may be transferred to their offspring, both prenatally (*via* trans-placental transfer) and postnatally *via* breast milk[3].
- The population burden of dioxin-like compounds should be monitored periodically, to see whether risk reduction strategies are effective.

Note that these recommendations are preliminary risk management recommendations made by the Office of Chemical Safety and they will be further developed following discussions with other government agencies and consideration of public input.

[2] Note that the relative specific heath risks of exposure to dioxins are low compared to those arising from a high intake of saturated fats

[3] As for dietary intake of saturated fats, the specific health risks associated with dioxin exposure are low compared to the known adverse effects of smoking

# 1. Introduction

Dioxins and related compounds are amongst the most studied of all chemicals. This interest arises because of the range of biological effects that they have been reported to cause in animal studies and in heavily exposed human cohorts, their potential to increase the incidence of cancers in people occupationally exposed to high levels of dioxins, their long half-lives in the environment and the human body, and the widespread and ubiquitous exposure of animals and humans to this class of compounds. Since dioxins are fat soluble, chemically stable and poorly metabolised, they can concentrate in body fat and build up under conditions of long-term exposure, both in animals and humans, and accumulate as they move through the food chain. These properties mean that even low levels of dioxins in the environment may eventually pose risks to animals and humans.

Although the exact impact of dioxins on people's health is not yet known, there are currently no clear indications that dioxins are causing increased disease in the general population.

International studies have concluded that around 95% of human exposure occurs through the consumption of food. People may also have some limited exposure through other routes such as breathing in air contaminated by dioxins in smoke (from bushfires, domestic wood heaters and cigarettes), factory or incinerator emissions, motor vehicle exhaust fumes, or from uncontrolled hazardous waste sites containing dioxins (eg. Furst et al 1992a; Liem et al 2000; US EPA 2000).

In Australia, available data suggest the levels of dioxins in the environment are generally low. In 1998 the Australian Government Department of Environment and Heritage produced an inventory of dioxins emissions to air. However, since only limited Australian data were available, this inventory had to use information from other countries to estimate dioxin emissions. In order to better understand how dioxins may be affecting human health and the environment in Australia, the Australian Government announced, in the 2001-02 Australian Government Budget, the decision to fund the conduct of a National Dioxins Program (NDP). It was agreed that the information gathered by the NDP would be used to estimate the extent to which people are exposed to dioxins, and determine the best actions Australia could take to reduce population exposure to dioxins.

The NDP has three phases. Phase One involved surveys of dioxin levels in the environment (air, soil, sediments, fauna) and people (plasma levels in people from various age groups and regions, and breast milk levels in first-time mothers) throughout Australia, in order to provide information to be used in the preparation of a new inventory of dioxins in Australia. Studies also assessed the contribution of bushfires, motor vehicles and domestic wood heaters to levels of dioxins in air. A survey of dioxin levels in foods was conducted by Food Standards Australia New Zealand (FSANZ). Phase Two used the findings of Phase One to provide the basis for assessing the potential risks of dioxins to the environment, as well as the potential risks for human health from exposure to dioxins either directly from the environment or from dioxin-contaminated food. Phase Three will use the Phase-Two risk assessments to develop

national management strategies to reduce, and where feasible, to eliminate the release of dioxins in Australia.

This document contains the results and conclusions of the Phase-Two human health risk assessment. It is structured into four main parts. The first part provides an overview of the known and possible effects of dioxins in animals and humans and considers a suitable intake level at which significant health effects are not expected to occur. The second part estimates likely dioxin intakes for the majority of the Australian population. The third part compares the estimated intakes with the health-based tolerable intake level and provides comment on likely health risks for the population. The final part of the report makes some suggestions for risk management measures aimed at reducing population exposures to dioxins and related compounds.

## 1.1 Overview

Much of the following overview text is taken from 'Dioxins: Recommendation for a Tolerable Monthly Intake for Australians' (NHMRC/TGA, 2002) and the references cited therein. Additional references used here are indicated. A number of published review volumes (eg. Schecter & Gasiewicz, 2003) provide useful reference information on the chemistry, toxicology and health effects of dioxins.

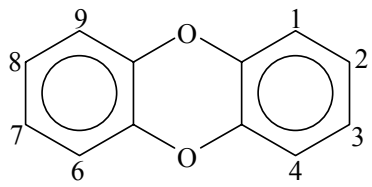
### 1.1.1 What are 'dioxins'?

The term 'dioxins' is used to describe a group of environmentally persistent halogenated aromatic hydrocarbon chemicals that includes polychlorinated dibenzodioxins (PCDDs), polychlorinated dibenzofurans (PCDFs), polybrominated dibenzodioxins (PBDDs), polybrominated dibenzofurans (PBDFs) and polychlorinated biphenyls (PCBs). The chlorinated compounds predominate and it is these which are the focus of this report. PCDDs, PBDDs, PBDFs and PCDFs are not manufactured intentionally but are by-products of combustion. They are formed naturally by volcanoes and forest fires, as well as by industrial processes such as waste incineration and the synthesis of certain chemicals. PCBs, on the other hand, were manufactured for approximately 50 years for use as components of insulating fluids in transformers and other electrical equipment.

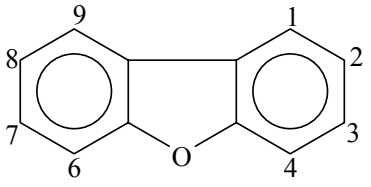
The potential toxicity of dioxins began to be recognised over 40 years ago. Concern over the potential adverse effects of dioxins has been amplified by evidence that they are resistant to metabolism and tend to remain in the body fat of animals and humans for a long time. The different structurally related chemicals (referred to as congeners) that make up the dioxins have half-lives that vary from 3.7 years for the least persistent type to 50 years for the most persistent, with an average half-life of approximately 7 years.

### 1.1.2 Chemistry and physicochemical properties of PCDDs, PCDFs and PCBs

The PCDDs and PCDFs are chlorinated tricyclic aromatic hydrocarbons, made up of two benzene rings joined by either two oxygen atoms at adjacent carbons on each of the benzene rings (PCDDs) or by one oxygen atom and one carbon-carbon bond (PCDFs); their basic structures are given in Figure 1-1.



Dibenzo-*p* -dioxin



Dibenzofuran

**Figure 1-1 Structures of dibenzo-p-dioxin and dibenzofuran**

Both groups of chemicals may have up to eight chlorine atoms attached at carbon atoms 1 to 4 and 6 to 9. Each individual compound resulting from this is referred to as a congener. Each specific congener is distinguished by the number and position of chlorine atoms around the aromatic nuclei. In total, there are 75 possible PCDD congeners and 135 possible PCDF congeners; groups of congeners with the same number of chlorine atoms are known as homologues. The number of congeners in each homologue group is shown in Table 1-1 (Müller et al, 2003a; Gilpin et al, 2003). The most widely studied of the PCDDs and PCDFs is 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). This congener is often generically referred to as 'dioxin', and represents the reference compound for this class of chemicals.

**Table 1-1 Homologues and congeners of PCDDs and PCDFs**

| Homologue name | Abbreviation | No. of possible congeners | No. congeners with Cls at 2, 3, 7 & 8 positions |
|---|---|---|---|
| Monochlorodibenzo-*p*-dioxin | MCDD | 2 | 0 |
| Dichlorodibenzo-*p*-dioxin | DiCDD | 10 | 0 |
| Trichlorodibenzo-*p*-dioxin | TrCDD | 14 | 0 |
| Tetrachlorodibenzo-*p*-dioxin | TCDD | 22 | 1 |
| Pentachlorodibenzo-*p*-dioxin | PeCDD | 14 | 1 |
| Hexachlorodibenzo-*p*-dioxin | HxCDD | 10 | 3 |
| Heptachlorodibenzo-*p*-dioxin | HpCDD | 2 | 1 |
| Octachlorodibenzo-*p*-dioxin | OCDD | 1 | 1 |
| | | | |
| Monochlorodibenzofuran | MCDF | 4 | 0 |
| Dichlorodibenzofuran | DiCDF | 16 | 0 |
| Trichlorodibenzofuran | TrCDF | 28 | 0 |
| Tetrachlorodibenzofuran | TCDF | 38 | 1 |
| Pentachlorodibenzofuran | PeCDF | 28 | 2 |
| Hexachlorodibenzofuran | HxCDF | 16 | 4 |
| Heptachlorodibenzofuran | HpCDF | 4 | 2 |
| Octachlorodibenzofuran | OCDF | 1 | 1 |

Congeners containing one, two or three chlorine atoms are thought to be of no toxicological significance. However, 17 congeners with chlorine atoms substituted in the 2, 3, 7 and 8 positions (i.e. in the lateral positions of the aromatic rings) are thought to pose a health and environmental risk. Increasing substitution from four to eight

chlorine atoms generally results in a marked decrease in their ability to cause biological effects of concern.

The PCBs are structurally similar to the PCDD/PCDFs and include 209 congeners, from the monochloro congener through to the fully chlorinated decachloro congener; the basic aromatic nucleus is shown in Figure 1-2. The distribution of PCB congeners arising from attachment of chlorine atoms to this nucleus is given in Table 1-2.

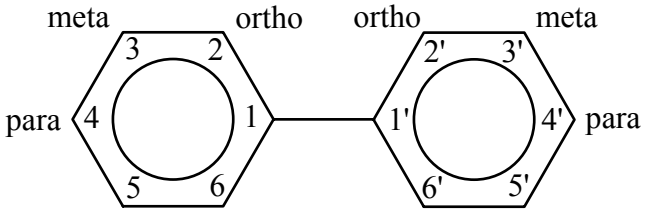


**Figure 1-2 Structure of biphenyl**

**Table 1-2 Distribution of PCB congeners**

| **No. of Cl substituents** | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|---|---|---|---|---|---|---|---|---|---|---|
| **No. of congeners** | 3 | 12 | 24 | 42 | 46 | 42 | 24 | 12 | 3 | 1 |

Like the PCDD/PCDFs, the biological effects of the PCBs are very dependent both on the degree of chlorination and on the position of the chlorine atoms around the aromatic nuclei (i.e. whether they are *ortho*-, *meta*- or *para*- to the phenyl-phenyl bridge at carbon-1). Certain PCBs, the non-ortho and mono-*ortho* congeners, can adopt a coplanar conformation that is structurally similar to the PCDD/PCDFs and appear to elicit dioxin-like responses through a similar mechanism of action. The non-*ortho* PCBs lack a chlorine substituent in any of the 2, 2', 6, or 6' positions while the mono-*ortho* PCBs have a single chlorine atom in any one of the 2, 2', 6, or 6' positions (see Table 1-3).

**Table 1-3 Names of the 12 dioxin-like PCBs**

| **PCB Name** | **PCB No.** |
|---|---|
| Non-*ortho* PCBs | |
| 3,3',4,4'-Tetrachlorobiphenyl | PCB 77 |
| 3,4,4',5-Tetrachlorobiphenyl | PCB 81 |
| 3,3',4,4',5-Pentachlorobiphenyl | PCB 126 |
| 3,3',4,4',5,5'-Hexachlorobiphenyl | PCB 169 |
| Mono-*ortho* PCBs | |
| 2,3,3',4,4'-Pentachlorobiphenyl | PCB 105 |
| 2,3,4,4',5-Pentachlorobiphenyl | PCB 114 |
| 2,3',4,4',5-Pentachlorobiphenyl | PCB 118 |
| 2,3',4,4',5'-Pentachlorobiphenyl | PCB 123 |
| 2,3,3',4,4',5-Hexachlorobiphenyl | PCB 156 |

| | |
|---|---|
| 2,3,3',4,4',5'-Hexachlorobiphenyl | PCB 157 |
| 2,3',4,4',5,5'-Hexachlorobiphenyl | PCB 167 |
| 2,3,3',4,4',5,5'-Heptachlorobiphenyl | PCB 189 |

PCDDs, PCDFs and dioxin-like PCBs are commonly referred to as 'dioxin-like compounds'.

In general, dioxin-like compounds have very low water solubility, high octanol-water partition coefficients, low vapour pressure and adsorb strongly to particles and surfaces (high $K_{OC}$) and are resistant to chemical degradation under normal environmental conditions. Thus, they are persistent in the environment and their high fat solubility results in their bioconcentration into biota and biomagnification up the food chain. Almost all 210 individual PCDD and PCDF congeners have been identified in emissions from thermal and industrial processes and consequently they are found as mixtures in environmental matrices such as soil, sediment, air, plants and lower animals, although their low aqueous solubility means they can hardly be detected in water and are largely immobile in soils.

The 'Illustrated Handbook of Physical Properties and Environmental Fate for Organic Chemicals', volumes 1 and 2 (Mackay et al, 1992a, 1992b) are useful references which provide data on the physical and chemical properties of dioxins and dioxin-like compounds, including water solubility, vapour pressure, Henry's Law constant, octanol-water partition coefficient and bio-accumulation factor. They include excellent illustrative examples about the partitioning behaviour of these contaminants in the environment.

### 1.1.3 Toxic equivalency factors

When found in the environment, biological tissues and industrial sources, dioxins are usually present as complex mixtures; this complicates hazard and risk assessment because the different congeners vary significantly in their toxicity. However, the potency of different dioxins can be ranked relative to TCDD, the most toxic member of the dioxin class. These rankings are known as toxic equivalency factors (TEFs). To be included in the TEF scheme, a compound must be structurally related to PCDDs and PCDFs, bind to the cellular aryl hydrocarbon (*Ah*) receptor, elicit *Ah* receptor-mediated biochemical and toxic responses, must be persistent, and accumulate in the food chain (WHO, 1998).

Several schemes for assigning TEFs to PCDD/Fs and PCBs have been used previously. However, the most recent review of TEFs was that of the WHO in 1998 (Van den Berg et al, 1998) (see Appendix XVIII for a comparison of TEF schemes). This review has subsequently been recognised by the United States Environmental Protection Agency (US EPA 2000) an many other countries (including Japan, Canada and the EU) as being the most appropriate scheme for estimating the toxicity of dioxin mixtures. Under the WHO TEF scheme shown in Table 1-4, TCDD is assigned a TEF of 1.0, and other PCDDs, PCDFs and PCBs have TEF values ranging from 1.0 down to 0.00001. To estimate the toxic potency of a given dioxin mixture, the mass concentration of each

individual component is multiplied by its respective TEF, and the products are summed to represent the TCDD toxic equivalence (TEQ) of the mixture. These TEFs will be periodically reviewed.

Throughout this document, the intake of dioxins will be expressed in units of TEQs, applying the 1998 WHO TEFs, unless they were derived using the previous international TEF scheme (US EPA, 1989), which is abbreviated as I-TEQ.

**Table 1-4 WHO TEFs for human risk assessment**

| Congener | TEF value | Congener | TEF value |
|---|---|---|---|
| ***Dibenzo-p-dioxins*** | | ***Non-ortho PCBs*** | |
| 2,3,7,8-TCDD | 1 | PCB 77 | 0.0001 |
| 1,2,3,7,8-PnCDD | 1 | PCB 81 | 0.0001 |
| 1,2,3,4,7,8-HxCDD | 0.1 | PCB 126 | 0.1 |

| 1,2,3,4,7,8,9-HpCDF | 0.01 | | |
| OCDF | 0.0001 | | |

Note: TEFs are based on the conclusions of the WHO meeting in Stockholm, Sweden, 15-18 June 1997 (Van den Berg *et al,* 1998).

The database on many of the polybrominated compounds has been less extensively evaluated, and these compounds have not been assigned TEFs by the WHO. Consequently, polybrominated compounds have not been explicitly considered in this assessment, which focuses on PCDDs, PCDFs and PCBs. Evaluation of the most common chlorinated congeners is generally considered to be sufficient to characterise environmental dioxins. PBDDs and PBDFs could be included in future assessments if sufficient information becomes available and inclusion is considered desirable on toxicological grounds (see eg. Birnbaum et al, 2003).

TEFs are based on the present state of our knowledge and it is likely that some values may be revised as new data becomes available. It should be noted that the widely-accepted approach of combining TEFs into a single exposure metric (TEQ) is not

without controversy, considered by some to be a simplistic approach to dealing with complex mixtures of dioxin-like compounds (eg. Starr, 2003). For example, some congeners may act as *Ah*-receptor antagonists, blocking or altering the effects of other congeners.

It is recognised that in addition to synthetic halogenated aromatic hydrocarbons, there are a number of quite potent natural compounds that can interact with the *Ah* receptor. These include indole-3-carbinol (IC3) and related compounds from cruciferous vegetables. Polycyclic aromatic hydrocarbons (PAHs) and other aromatic amines formed during cooking can also interact with the *Ah* receptor, and may further complicate risk assessment (Safe, 1998). However, it is still unknown whether these compounds exert a significant influence on the toxicity of dioxins, and their possible effects cannot be assessed at present.

### 1.1.4 Exposure

Dioxins are ubiquitous in the environment, being found throughout the industrialised world in air, soil and sediments, as well as in food. Human exposure to dioxins can occur through working in industries in which they are by-products, from industrial accidents, and through food (including breast milk). Intake *via* inhalation and dermal absorption is likely to represent a very small source of exposure to dioxins.

Exposure of the general public to dioxins is predominantly through the diet, with food of animal origin being the major source. Contamination of food is primarily caused by dioxin emissions to the atmosphere from various industrial or thermal processes (eg. bushfires, wood heaters, waste incineration, production of chemicals), with subsequent deposition onto farmland and water bodies, followed by bioaccumulation up terrestrial and aquatic food chains. Other sources of dioxin-like chemicals can include contaminated stockfeed (for cattle, chicken and farmed fish), improper application of sewage sludge to agricultural land, flooding of pastures, waste effluents and certain types of food processing.

Based on measured concentrations of dioxins, furans and PCBs in food, and data on national food consumption, the 2001 JECFA evaluation estimated that median long-term intakes of PCDDs and PCDFs are 33-42 pg TEQ/kg bw/month for adults living in the United States or Western Europe. Estimates for New Zealand and Japan derived from measured concentration and food supply data were significantly lower, at 18 and 7 pg TEQ/kg bw/month, respectively[4]. If dioxin-like PCBs are also included, the daily total TEQ intake increases by about 25 per cent in the United States and is approximately doubled in other regions. Recent studies from countries that started to implement measures to reduce dioxin emissions in the late 1980s, such as the Netherlands, UK and Germany, clearly show that dioxin levels in food have decreased since that time, with a consequent reduction in dietary intake of these compounds by a factor of almost 2 over a 7-year period (WHO, 1998). In Canada, regulatory and guideline initiatives have markedly reduced PCDD and PCDF emissions from waste incinerators and bleached kraft pulp mills, with consequent declines in the

[4] The New Zealand and Japanese estimates may be higher than the true intake, as food *supply* exceeds food *consumption* by at least 15 per cent.

concentrations of these chemicals in fish and shellfish (Larsen et al, 2000). Similar measures have been undertaken in other countries, including Australia.

On a bodyweight basis, the daily intake of dioxins for breastfed babies is reported to be significantly higher than that for adults. A WHO field study showed that mean levels of PCDD/PCDF and PCB in human milk were higher in industrialised areas (10-35 pg I-TEQ/g milk fat) than in developing countries (<10 pg I-TEQ/g milk fat) (WHO 1996). However, there is clear evidence of a decrease in PCDD/PCDF levels in human milk between 1988 and 1993, with the highest rates of decrease in areas with the highest initial concentrations (WHO, 1996).

Examples of accidental exposures of local populations to PCDDs, PCDFs and PCBs include the incident at Seveso, Italy, and fires in PCB-filled electrical transformers. High exposure may also be caused by accidental contamination of food eg. industrial contamination of edible food oil, such as occurred at Yusho (Japan) and Yu-Cheng (Taiwan). While many industrial sources of occupational exposure have been identified and worker exposures have been reduced or eliminated, historic median TCDD levels in blood of highly exposed workers have been 1-3 orders of magnitude higher than blood levels in the general population. Body burdens caused by accidental or occupational exposure are normally dominated by only a few congeners; congener patterns are different from background exposure arising primarily from indirect exposure through the food supply where bioaccumulation can modify congener patterns.

### 1.1.5 Mechanisms of toxicity

The *Ah* (for aryl hydrocarbon) receptor is important in mediating the biological and toxicological effects of TCDD and dioxin-like compounds. Although the precise chain of molecular events is not fully understood, alterations in key biochemical and cellular functions are likely to be responsible for dioxin toxicity. Activation of the *Ah* receptor has two major consequences: increased transcription of various genes (eg. those coding for drug-metabolising enzymes) and immediate activation of tyrosine kinases; tyrosine kinase enzymes catalyse the transfer of the phosphate of ATP to tyrosine residues on protein substrates including enzymes and receptors, thus affecting enzyme activity and receptor function. The *Ah* receptor can also regulate expression of other networks of genes, either directly or indirectly. Activation of the *Ah* receptor can result in endocrine and paracrine disturbances, and alterations in cell functions, including growth and differentiation. Some of these effects have been observed both in humans and animals, indicating the existence of common mechanisms of action in different species. Some of the ligands that bind the *Ah* receptor may block its activation by behaving as weak agonists, or antagonists (eg. Safe and McDougal 2002). This means that binding of the *Ah* receptor by some members of the dioxin class could conceivably block the action of other, more toxic congeners, complicating the risk assessment of dioxin mixtures.

### 1.1.6 Cellular targets for dioxins

A family of so-called ‘nuclear receptors’ (NRs) function to transduce chemical signals into transcriptional responses in the cell nucleus by controlling the activity of specific target genes.

These NRs can be activated (and repressed) by a range of endogenous chemicals including the steroid hormones, retinoids (active metabolites of vitamin A), vitamin D, thyroid hormone, glucocorticoids and mineralocorticoids, and various xenobiotics including aryl hydrocarbons.

As discussed above, the *Ah* (for aryl hydrocarbon) receptor, a ligand-activated transcription factor involved in the regulation of a large number of genes, is considered to be a key site in mediating the biological and toxicological effects of TCDD and dioxin-like compounds.

TCDD and other PAHs exert effects on retinoid, thyroid hormone and vitamin D metabolism at very low doses following TCDD exposure (Hoegberg et al, 2003; Lilienthal et al, 2000; Nilsson & Hakansson, 2002; Van Birgelen et al, 1995). Likewise, a recent study has demonstrated that the agonist-activated AhR/Arnt[5] heterodimer directly associates with estrogen receptors, suggesting a novel mechanism of estrogenic signalling modulation (Ohtake et al, 2003).

### 1.1.7 Kinetics of dioxins and the concept of body burden

The fate of dioxins in the body is unusual, primarily because most of the congeners are extremely fat soluble but are practically insoluble in water. Following ingestion and absorption from the small intestine, dioxins are readily distributed via the blood to all organs, but they are preferentially retained in adipose (fatty) tissue. The release of stored dioxins from adipose tissue into the circulation is extremely slow, limiting the rate of metabolism by the liver and subsequent excretion in the faeces via the bile. Hence, the time to excrete half of an ingested dose of dioxins (the half-life) is usually measured in years. As discussed above, dioxins are composed of a mixture of compounds and each has a different half-life, but the commonly quoted average in humans, based on data from Seveso, ranges between 7 and 10 years.

The long half-life of dioxins means that, over decades, even a low rate of exposure leads to accumulation of dioxins in the body. Continual exposure from contaminated food might lead in the long term to an extremely high body burden (i.e. the total amount of dioxins in the body). Therefore, it is important to minimise the levels of dioxins in food. The capacity of humans to store dioxins in fat is so great that it would be expected to take 40–50 years to reach a balance or steady state, where the rate of intake equals the rate of excretion. Thus, a few exposures that exceeded the accepted dietary limit by ten- or even a hundred-fold would not significantly change a body burden accumulated over several decades. A single dose of dioxins of 5000 pg or a lifelong intake of around 1 pg/day would result in a similar body burden.

The biochemical and toxicological effects of dioxins, furans and PCBs relate more closely to their concentration in the target tissue than to the daily dose. Dioxins accumulate in vital organs and therefore it is difficult to directly measure the concentration in particular tissues except at post-mortem. However, the body burden of dioxins correlates strongly with levels in adipose tissue and serum and can, therefore, be readily estimated by measuring dioxin levels in adipose tissue or serum, or estimated

[5] Arnt = aryl hydrocarbon receptor nuclear translocator

from the ingested dose. Also, it has been assumed that data on body burden overcomes interspecies differences in the absorption, distribution, metabolism and excretion of dioxins. Therefore, the consultations by the WHO, the EC-SCF and JECFA concluded that the body burden is the measurement of choice for comparing risks between humans and animals. JECFA concluded that the appropriate averaging period for evaluating intake of these compounds is one month or more, whereas the EC-SCF favoured an interval of one week.

# 2. Hazard Assessment

## 2.1 Introduction

This chapter contains summary information about the hazards (or intrinsic toxicity) of dioxins and related compounds. It is not a risk assessment, which estimates the likely exposure of the population to dioxins and compares that intake with estimated safe intake levels which are established from a knowledge of the toxic effects of the compounds and the doses at which these effects are likely to occur. It updates the information contained in the 2002 hazard assessment overview which recommended an Australian TMI for dioxins (NHMRC/TGA, 2002) by considering relevant research on dioxins conducted since the 2002 report, as well as recent assessments and reports prepared by other national and international organisations or agencies. Note that this document is not a *de novo* hazard assessment but a summary overview report. Furthermore, its focus is on findings from in vivo studies in animals and clinical and epidemiology studies in humans; therefore it does not consider mechanism-of-action or in vitro studies.

A considerable number of comprehensive reviews of the toxicology of dioxins and dioxin-like compounds have been written in recent years. The 1998 review of dioxins by the Agency for Toxic Substances and Disease Registry (ATSDR) of the Public Health Service of the US Department of Health and Human Services is one of the most comprehensive reviews of the subject to date. The information in the 'Overview' (Section 2.2) is largely taken from a number of reviews including that of the ATSDR (ATSDR, 1998), the reports of the meetings of the 1998 WHO-ECEH/IPCS consultation (WHO, 1998; Van Leeuwen et al, 2000a & b), the EC-SCF (EC Scientific Committee on Food, 2001) and JECFA (FAO/WHO, 2001). To update these reviews, a monograph on Dioxins and Health (Schecter & Gasiewicz, 2003) provided a useful information source. Information contained in Section 2.3 ('Summary of the Toxicity of Dioxins') includes results of a literature search (conducted in September 2003) on the human health effects of dioxins[6].

[6] The search, conducted by Ms Kristen Dyer, was based on retrieving articles dealing primarily with risk assessment, excluding articles on dioxin levels in food, soil, animals, people; bio-monitoring of dioxins in humans; and managing dioxins. Databases searched included: Medline; Medline-in-process; Embase; Biosis (Biological Abstracts); Elsevier Biobase (Current Awareness in Biological Sciences); Toxline; EnviroLine; AMI (Australasian Medical Index); plus the catalogue of the Australian Government Department of Health and Ageing library.

## 2.2 Summary of the Toxicity of Dioxins

### 2.2.1 Animal data

*2.2.1.1 Key studies*

Numerous published studies have documented a variety of adverse effects of TCDD in experimental animals. The following Table lists a number of studies which have been pivotal in establishing human health guidelines for exposure to dioxin-like compounds.

**Table 2-1 Some key toxicity studies used in the derivation of human health criteria**

| Study | Species/Strain | Biological effect |
|---|---|---|
| Kociba et al, 1978 | Rats, Sprague-Dawley | Cancer |
| Schantz & Bowman, 1989; Schantz et al, 1992 | Monkeys, Rhesus | Neurobehavioural effects in offspring |
| Mably et al, 1992a, b | Rats, Holzman | Decreased sperm counts in offspring of treated dams; decreased weights of testis and accessory sex organs |
| Rier et al, 1993 | Monkeys, Rhesus | Endometriosis |
| Gray et al, 1997a | Rats, Long Evans Hooded | Accelerated eye opening and decreased sperm counts in male offspring |
| Gray et al, 1997b | Rats, Long Evans Hooded | Increased genital malformations in female offspring |
| Gehrs et al, 1997; Gehrs & Smialowicz, 1999 | Rats | Immune suppression in offspring |
| Faqi et al, 1998 | Rats, Wistar | Decreased sperm production and altered sexual behaviour in male offspring |
| Ohsako et al, 2001 | Rats, Holzman | Decreased anogenital distance in male offspring |

Adverse effects reported in animals following exposure to dioxins include immunotoxicity, endometriosis in Rhesus monkeys, developmental behavioural developmental effects in offspring of treated Rhesus monkeys, and developmental effects in rats (including reproductive toxicity in males and urogenital malformations in females).

The results of a two-year carcinogenesis bioassay conducted by Kociba et al (1978) have been the most often utilized for cancer risk assessment of TCDD. Sprague Dawley rats of both genders were given 2,3,7,8-TCDD (99% pure) in the feed to achieve intakes of 0, 1, 10 and 100 ng/kg bw/day. Results indicated that at 100 ng/kg bw/day, TCDD

caused an increase in the incidence of hepatocellular hyperplastic nodules and carcinomas in female but not in male rats. At this dose, statistically significant increases in squamous cell carcinomas of the lungs (females) and tongue and nasal palate/nasal turbinates (males) were also reported. Conversely, at this dose there was a significant reduction in the incidence (in female rats) of spontaneous benign tumours of the uterus, benign and malignant mammary tumours and pituitary adenocarcinomas, and (in male rats) adrenal gland phaeochromocytomas and pancreatic adenomas. Although the mechanisms for such reductions in tumour incidence are not well understood, reductions in body weight[7] as a result of TCDD exposure and disruption of endocrine homeostasis have been suggested as two possible reasons for these findings.

There was also a reduction in the incidence and severity of chronic renal disease in aged male rats. At the mid dose (10 ng/kg bw/day) there was no evidence of TCDD effects on tumour incidence, although an increased incidence of hepatocellular nodules was observed. Lifetime ingestion of TCDD at the low dose (1 ng/kg bw/day) did not cause any effects considered to be of toxicological significance. A re-evaluation of liver specimen slides from the female animals was performed by a pathology panel (Keenan et al, 1991). They found about two-thirds fewer tumours present in the livers of female rats than in the original report. The panel established a NOEL for hepatocellular carcinomas of 10 ng/kg bw/day. A further review of the slides (Goodman & Sauer, 1992) substantially confirmed results showing a dose-related increase in tumour incidence (hepatocellular adenomas - 2/81 control; 1/50 low-dose; 9/50 mid-dose; and 14/45 high-dose: hepatocellular carcinomas - 0/86, 0/50; 0/50 and 4/45: hepatic eosinic foci - 31/86; 23/50; 37/50 and 40/45).

In a developmental toxicity in rhesus monkeys (Schantz et al, 1992), groups of 8 female rhesus monkeys were fed a diet containing 0, 5, or 25 ppt TCDD for a total of 16.2 months, throughout the mating period, gestation, and lactation. After 7 months of exposure, the monkeys were mated with unexposed males (to a maximum of 10 matings) until conception occurred, with dosing continuing during mating, gestation and lactation. Only 1 monkey in the 25 ppt group delivered a viable offspring; this offspring was not studied behaviourally. When the offspring (3 males and 3 females per exposure group) were 8.6 months of age, they were placed in 3 peer groups of 4 monkeys and allowed to play for 1.5 hours without interference. The peer groups consisted of two TCDD-exposed monkeys and two control monkeys. Behavioural patterns (social interactions and other behaviours such as vocalisation, locomotion, self-directed behaviour, and environmental exploration) were monitored 4 days/week for 9 weeks. No overt signs of toxicity were observed in the mothers or offspring and birth weights and growth were not adversely affected by TCDD exposure. Significant alterations were observed in play behaviour, displacement, and self-directed behaviour in the TCDD-exposed offspring; they tended to initiate more rough-tumble play bouts and retreated less from play bouts than controls, were less often displaced from preferred positions in the playroom than the controls, and engaged in more self-directed behaviour than controls. No other significant alterations in behaviour or alterations in reflex development, visual exploration, locomotor activity, or fine motor control were found (Bowman et al, 1989b). In tests of cognitive function, object learning was significantly

[7] Actual bodyweight changes not provided in the Kociba et al (1978) paper.

impaired, but no effect on spatial learning was observed (Schantz & Bowman, 1989). The dietary level of 5 ppt was stated to be equivalent to an intake of 120 pg/kg bw/day.

Ten years after termination of approximately 4 years of TCDD exposure in female Rhesus monkeys [maternal animals from the Shantz et al (1992) study summarised above], Rier et al (1993) reported a dose-related increase in the incidence and severity of endometriosis, and identified a lowest observed adverse effect level (LOAEL) of 5 ppt in the diet (120 pg/kg bw/day) for moderate endometriosis.

In studies in Holzman rats, Mably et al (1992a, b) found significant decreases in daily sperm production and the amount of mature sperm stored in the cauda epididymis of rats exposed prenatally to a single dose of 2,3,7,8-TCDD on gestational day (GD) 15; in rats, day 15 corresponds to the onset of the endocrine-sensitive phase of sexual differentiation. Decreases in weights of testis, cauda epididymis, ventral prostate and seminal vesicle were observed in juvenile, pubertal, post-pubertal, and sexually mature rats prenatally exposed to TCDD on GD 15. The lowest LOAEL for these effects (decreased testis weight) was 64 ng/kg bw, identified in the Mably et al (1992c) study. The effects do not appear to result from reduced plasma androgen concentrations during the perinatal period as originally proposed and do not completely correspond with the developmental effects of known anti-androgens (Theobald et al, 2003).

Gray et al (1997a) investigated the reproductive effects of TCDD administration on GD 15 in male Long Evans Hooded rat offspring. Pregnant dams were dosed by gavage with 0, 0.05, 0.20 or 0.80 µg/kg bw TCDD in corn oil. Male offspring (10-12/group) were monitored for viability, growth, and reproductive function. Accelerated eye opening was observed in all dose groups cf. controls (50% of the animals in the low and mid-dose groups and 79% in the high-dose group). Reduced pup survival and growth retardation were observed in offspring from the high-dose group. Percentage pup survival on days 3 to 22 ranged from 82% to 93% at the high dose whilst survival in all other dose groups (including controls) was 99-100%. The most sensitive adverse effect was a 25% reduction in ejaculated sperm numbers at the lowest dose tested (0.05 µg/kg bw). The number of animals affected was not reported.

Gray et al (1997b) also investigated the effects of a single dose of TCDD on GD 15 on female offspring of Long Evans Hooded rats (18-24 pups/dose group). Delayed vaginal opening was observed in progeny from dams exposed to 0.80 µg/kg bw. The mean distance from urethral to vaginal opening was 6.8 mm in the high-dose group *vs* 11.03 mm in controls. A dose-related increase in the percentage of females with a temporary or persistent vaginal thread was observed, from 15% in control animals to 97% in the highest exposure group. The threads were permanent in 2.5% of controls, as compared to 10%, 27%, and 92% of offspring from the 0.05, 0.20 and 0.80 µg/kg bw groups respectively; at the two highest doses, the increases were statistically significant. Partial to complete clefting of the phallus was displayed in offspring at 0.20 (20% of offspring) and 0.80 µg/kg bw (75%). Other morphological changes in animals from these dose groups were increased length of the urethral slit, increased distance from the urethral opening to the tip of the phallus, and decreased distance from the urethral opening to the vaginal orifice. Time to pregnancy was delayed in female offspring from the high-dose group, although fertility rate was not affected. Histopathological changes in the ovary,

cervix, and vagina were observed in animals necropsied at 20 months of age. The investigators noted that GD 15 might not have been the most sensitive for the detection of ovarian alterations, endometrial hyperplasia, and a shortened reproductive life span.

Gehrs et al (1997) and Gehrs and Smialowicz (1999) studied the persistence of delayed-type hypersensitivity (DTH) suppression in the offspring of Fischer 344 rats exposed to TCDD by gavage at 0, 0.1, 0.3 or 1.0 µg/kg bw on GD 14. DTH suppression was determined by measuring the DTH response to bovine serum albumin in the offspring at 4 to 19 months of age. TCDD significantly suppressed the DTH response in males at up to 19 months of age. While the females' DTH response was reduced at 8, 12 and 19 months, significant suppression was observed only at 4 months of age. The lowest maternal dose of TCDD that produced DTH suppression was determined by measuring the DTH response to BSA in 4- and 14-month-old offspring of dams dosed orally with 0, 0.1, 0.3 or 1.0 µg/kg kg bw on GD14. In males, suppression was observed at a maternal dose as low as 0.1 µg/kg bw at 14 months of age, while a maternal dose of 0.3 µg/kg bw was necessary to cause suppression in the 14-month-old females. It was concluded that suppression of the DTH response associated with perinatal TCDD exposure persists through late adulthood, occurs at low maternal doses (i.e. 0.1 µg/kg bw), and is more pronounced in male than in female rats. Whilst differences in subsets of thymocytes and lymph node cells were noted between control and TCDD exposed offspring, no clear correlation was established between altered subpopulations of thymic cells and suppressed DTH responses.

The animals most sensitive to dioxin-induced adverse effects were the male offspring of Wistar rats (Faqi et al, 1998). In this study, dams received an initial loading dose of 25, 60 or 300 ng $^{14}$C-TCDD/kg bw two weeks prior to mating, followed by weekly maintenance doses of 5, 12 or 60 ng/kg bw throughout mating, pregnancy and lactation. These maintenance doses were intended to prevent the maternal body burdens from declining below 20, 48 and 240 ng/kg bw, respectively, assuming an elimination half-life of three weeks for TCDD in adult rats. The study failed to demonstrate a NOEL because decreased sperm production and feminised sexual behaviour were observed in male offspring of the lowest dose group at 70-170 days of age. By reference to toxicokinetic data in pregnant rats (Hurst et al, 2000a, b), the EC Scientific Committee on Food (EC-SCF) estimated a maternal steady-state TCDD body burden of 39 ng/kg bw in dams at lowest dose, which was taken as the LOEL. The Joint Expert Committee on Food Additives (JECFA) applied linear and nonlinear curve fitting to the same data, and arrived at maternal steady-state body burden estimates of 25 and 39 ng/kg bw, respectively.

The lowest NOEL was found in a reproduction study by Ohsako et al (2001) in which Holtzman rats received a single oral dose of 0, 12.5, 50, 200 or 800 ng TCDD/kg bw on the 15$^{th}$ day of pregnancy (GD 15). Male offspring displayed reduced anogenital distance and androgen receptor mRNA levels in the ventral prostate, with a LOEL of 50 ng/kg bw. The NOEL was 12.5 ng/kg bw. Assuming that 60 per cent of a single gavage dose was retained in the body at GD 16, the NOEL of 12.5 ng/kg bw and the LOEL of 50 ng/kg bw would result in maternal body burdens of 7.5 and 31 ng/kg bw, respectively. By reference to toxicokinetic data in pregnant rats (Hurst et al, 2000a, b),

JECFA estimated a maternal body burden of 13–19 ng/kg bw at the NOEL, with a corresponding estimate of 51–76 ng/kg bw at the LOEL.

The above NOEL should be protective with respect to another sensitive indicator of the effects of TCDD in animals, that of tooth development. Kattainen et al (2001) examined the effects of TCDD on tooth development in three rat lines that differ in their TCDD sensitivity and *Ah* receptor structure, derived from TCDD-resistant Han/Wistar (Kuopio) and TCDD-sensitive Long-Evans (Turku/AB) rats. The main target teeth were the third molars, since their development spans from the perinatal period to about 6 weeks after birth. Pregnant dams were exposed to 30 -1000 ng/kg bw TCDD on gestation day 15. Pups were euthanised at the age of 5 or 10 weeks and the jaws examined by stereomicroscopy and radiography. TCDD at 1000 ng/kg completely prevented the development of the third lower molars in 60% of males and 50% of females in the most sensitive rat line while <6% of pups in the more resistant lines lacked this target tooth. In the most resistant strain TCDD exposure also dose-dependently diminished the proportion of lower third molars which had erupted by the age of 5 weeks. In the other more sensitive strains, less than 30% of the lower third molars had partially or completely erupted by postnatal day 35. Molar size was dose-dependently reduced in the 3 lines; the third lower molars were most severely affected, with the reduction reported to be significant at 30 ng/kg bw in one of the less-sensitive lines and at 100 ng/kg bw in the other two lines (including the most sensitive one). The same investigators studied the effects of higher TCDD doses (single dose of 50 or 1000 µg/kg bw) given to dioxin-resistant Han/Wistar rat dams one day after delivery, so that pups had post-natal exposure during lactation (Lukinmaa et al, 2001). Pup heads were analysed radiographically or histologically at postnatal days 9 and/or 22. A greater proportion of pups at the higher dose lacked third molars (at the bud stage at the start of the experiment) than those at the lower dose (9/13 *vs* 1/6). The teeth of control pups developed normally. In contrast to controls, none of the 11 experimental pups examined radiographically (6 at the higher dose and 5 at the lower) showed mineralization of their third molar cusps. Results indicate that the effects of TCDD on rat tooth development depend not only on the dose but also on tooth type and developmental stage. It was suggested that the interference by TCDD with tooth morphogenesis with the consequent arrest of development is likely to involve epithelial-mesenchymal signalling.

Studies in rats have shown that TCDD can arrest molar tooth development after *in utero* and lactational exposure, and that the sensitive stage is temporally restricted. To define the stage at which TCDD is able to arrest tooth development and the cellular background of the effect, mouse embryonic molar tooth explants including early developmental stages from initiation to late cap stage were exposed to TCDD in organ culture. Results indicated that TCDD can arrest tooth development *in vitro* if the exposure starts at the initiation stage, whereas exposure at later stages leads to smaller tooth size and deformation of cuspal morphology. It appears that TCDD interferes with tooth development by stimulating apoptosis in those cells of the dental epithelium which are predetermined to undergo apoptosis during normal development (Partanen et al, 2004).

Pregnant rhesus monkeys aged 5-7 years were given TCDD subcutaneously on day 20 of gestation at an initial dose level of 0, 30 or 300 ng/kg bw (1 ml/kg vehicle). For

maintenance of body burden, 5% of the initial dose was administered every 30 days during pregnancy and lactation, until day 90 after birth. No abnormalities were detected in the control and 30 ng/kg groups whereas more than half of the young in the 300 ng/kg group had tooth abnormalities. The upper permanent lateral incisors were most frequently affected. Of the deciduous teeth, the central incisors seemed to be most sensitive to TCDD. The permanent premolars were also frequently affected, whilst the canines and the first molars were not. These results indicate that the LOAEL body burden for induction of tooth abnormalities in rhesus monkeys is greater than 30 ng/kg bw but less than 300 ng/kg bw. On the basis of this dose-response information, the authors (Yasuda et al, 2004) concluded that the current TDI for dioxins in Japan (4 pg/kg bw/d; equivalent to 120 pg/kg bw/month) "needs no immediate modification".

#### *2.2.1.2 Cancer*

Experimental studies demonstrate that TCDD is carcinogenic in all species and strains of laboratory animals tested. It has been characterised as a multi-site carcinogen. However, short-term studies have shown a lack of direct DNA-damaging effects, indicating that TCDD is not an initiator of carcinogenesis. It appears that that TCDD is not directly genotoxic but is a potent tumour promoter (see eg. Wyde et al, 2002) and as such, can give the appearance of being a complete carcinogen. Also, the ability of TCDD to enhance proliferation and inhibit apoptotic processes in focal hepatic lesions further supports an indirect mechanism of carcinogenicity. Of the organ systems positive for TCDD-mediated carcinogenesis in rodent bioassays, a complete mechanism of action has only been proposed for thyroid follicular cell carcinogenesis, and it is considered that humans would be less sensitive than rats to the induction of this tumour type by TCDD (Teeguarden & Walker, 2003). The WHO consultation (WHO, 1996) noted that the NOEL of TCDD for hepatic adenomas in a 2-year study in rats was 1 ng/kg bw/day at which dose the body burden was 60 ng/kg bw.

At this stage, the finding that TCDD reduces the incidence of some spontaneous tumours in rodents at some sites (see above discussion of the Kociba et al, 1978 results) and the mechanism(s) by which this occurs, is not well understood.

### 2.2.2 Human data

#### *2.2.2.1 Non-cancer endpoints*

The incidence of adverse health effects other than cancer has been, and is being evaluated in population groups exposed to dioxins, dioxin-like and non-dioxin-like polychlorinated aromatic compounds in a variety of exposure scenarios. Epidemiological data indicate that some conditions (eg alterations in metabolic parameters and mortality from cardiovascular and non-malignant liver disease) may be increased in exposed populations compared to the unexposed referent groups. However, of the range of non-cancer health effects evaluated in exposed adult populations, many were transient and not observed when exposure ceased. Populations exposed occupationally or environmentally to TCDD have not demonstrated any significantly increased all-cause or non-cancer mortality (Bertazzi et al, 1989; Cook et al, 1986, 1987; Fingerhut et al, 1991a, b; Ott et al, 1980, 1987; Wolfe et al, 1995; Zack & Suskind, 1980). Likewise, no overall excess mortality was reported in workers exposed

to TCDD as a result of an accident which occurred on 17 November 1953 at the BASF facility in Germany (Ott & Zober, 1996; Thiess et al, 1982; Zober et al, 1990).

The most widely recognised and consistently observed effect following high dose exposure to TCDD is chloracne (ATSDR, 1998; US EPA, 1994; Pesatori et al, 2003). The condition can disappear after termination of exposure or can persist for many years. Other effects on the skin include hyperpigmentation and hirsutism (Ashe & Suskind, 1950; Suskind & Hertzberg, 1984). In certain instances, effects persisted for several years. Increased levels of hepatic enzymes and slight alterations in lipid profile have been reported in humans exposed to high levels of TCDD (ATSDR, 1998), although the effects were mild and often transient. Temporary enlargement of the liver has also been observed (US EPA, 1994). TCDD can cause long-term alteration in glucose metabolism (Henriksen et al, 1997; Pesatori et al, 1998) and slight changes in thyroid function (Zober et al, 1994). Effects on the respiratory system, manifested mainly as upper respiratory tract irritation, have resulted from acute high exposure to TCDD (ATSDR, 1998). Other irritant effects resulting from acute exposure include conjunctivitis with red and irritated eyes, and blepharitis[8] (US EPA, 1994). There is some suggestive evidence of toxicity to the cardiovascular system (ATSDR, 1998; Steenland et al, 1999) and limited information regarding body weight effects in humans (ATSDR, 1998). Some of these effects are discussed in more detail below.

The most severe exposure of humans to TCDD is reported to have occurred in 1997 (Geusau et al, 2001a). Two office workers in a textile research institute in Vienna were exposed to massive TCDD intoxication from an unknown source (probably from prior synthesis of 2,4,5-trichlorophenol in the facility). Inadvertent exposure, probably by oral ingestion, most likely occurred in October 1997 with the most severely affected patient reporting to a dermatology clinic in March 1998. This 30-year-old female patient was shown to have the highest blood lipid level of TCDD ever recorded in a person, 144,000 pg/g blood lipid[9], corresponding to an estimated body burden of 1.6 mg of TCDD and a dosage of 25 µg/kg body weight. This patient suffered severe, persistent and disfiguring chloracne, but other than some gastrointestinal symptoms (nausea, vomiting, epigastric pain and loss of appetite, with gastritis confirmed by gastroscopy), only a few clinical and biochemical health effects were observed over the first 2 years of follow-up. There were moderate elevations of blood lipids, leukocytosis, and anaemia, but no evidence of a primary bone marrow disorder. The persistence of leukocytosis was most likely to be due to the inflammatory skin condition and the intermittent administration of corticosteroids rather than a direct effect of TCDD. Similarly, the persistence of anaemia was most likely to be due to the skin inflammation, although a direct effect of TCDD on erythropoiesis cannot be ruled out. Lymphocyte subset analysis showed a marginal decrease in the percentage of natural killer (NK) cells but several other immunological parameters were within normal limits. Detailed investigations ruled out any disturbance of the hypothalamic-pituitary axis. Pulmonary function, neurological, psychodynamic and electrophysiological examinations were unremarkable, as were

[8] A chronic or long-term inflammation of the eyelids and eyelashes. Among the most common causes are poor eyelid hygiene; excess oil produced by the glands in the eyelids; bacterial infection; and an allergic reaction.

[9] The highest previously reported human levels of TCDD were 10,400 pg/g blood fat in an adult and 56,000 pg/g in a child, arising from the Seveso incident.

chest X-rays and abdominal ultrasound. Menstruation ceased in late autumn 1997 (the presumed time of intoxication) and secondary amenorrhoea was still present in late 2000 after she stopped using contraceptives in summer 1999. This amenorrhoea may be due to TCDD inhibition of estradiol synthesis or its cytochrome P450-mediated metabolism, or to hyperprolactinaemia which coincided with the initiation of antidepressant therapy with 5HT antagonists which are known to increase prolactin levels. The second patient, a 27-year-old woman, was also highly intoxicated with TCDD, 26,000 pg/g of blood lipid, but apart from some mild facial chloracne (cleared within a year, following treatment with topical tretinoin) and gastrointestinal symptoms, she was apparently largely unaffected. Routine laboratory and immunological parameters were within the normal range, apart from marginally elevated cholesterol and lipase, an elevated number and percentage of B lymphocytes and a decreased percentage of NK cells. Three other workers with elevated blood levels of 856, 149 and 93 pg/g blood lipids were asymptomatic. The estimated intakes for the two highly-exposed patients significantly exceed the estimated median lethal dose of dioxin (0.6 - 2.0 μg/kg bw) in guinea pigs, the most sensitive species tested. However, long-term follow-up of these patients will be necessary to assess the occurrence of chronic sequelae, including cancer.

Additional references on these two clinical cases include Geusau et al (1999), Geusau et al (2001b), Geusau et al (2002), and Abraham et at (2002).

#### *2.2.2.2 Chloracne*

As noted above, the most consistent observation following human exposure to TCDD is chloracne. Mocarelli et al. (1991) described chloracne in people from Zone A in Seveso who had serum TCDD levels ranging from 828 to 56,000 ng/kg lipid. With the exception of one person who developed less severe chloracne, all people who had lipid-adjusted TCDD levels over 12,000 ng/kg (ppt) developed severe chloracne. Several people with levels below 12,000 ppt developed less severe chloracne; the lowest reported TCDD level associated with chloracne was 828 ppt at the time of the accident. In the group that developed chloracne, >95% were under 20 years old, including the person with the lowest reported serum lipid TCDD concentration. In fact, children appear to develop chloracne at lower serum TCDD concentrations than adults (Assennato, 1989; Mocarelli et al, 1991). One reason for the observed variability with respect to the blood concentration of TCDD associated with chloracne is that some people absorbed much of their dose *via* dermal contact while others ingested the dioxin. It appears that the blood level which can produce chloracne can be much smaller if it arises from dermal contact rather than from oral ingestion. Nevertheless, it appears likely that a dose threshold needs to be overcome in order for chloracne to occur (Greene, Hays & Paustenbach, 2003). In the case of the very highly-exposed office worker in Vienna (144,000 ng/kg blood lipid; Geusau et al, 2001a; see above), the chloracne cysts were subject to recurrent deep inflammation, requiring surgical removal of comedones and treatment with methyl-prednisolone, analgesics and antibiotics. In the second highly-exposed patient (26,000 ng/kg blood lipid) there were only mild manifestations of chloracne. This was attributed to the exposure most likely being by the oral rather than the dermal route, and supporting the suggestion that, in the absence of direct skin contamination, higher systemic threshold levels may be necessary for chloracne to develop.

#### *2.2.2.3 Diabetes etc*

Data from several epidemiological studies suggest that significant exposure to TCDD increases the risk of diabetes mellitus, resulting from decreased cellular glucose uptake. Follow-up assessment of the population exposed to dioxin after the 1976 accident in Seveso, Italy, was extended to 1996. An overall increase in diabetes was reported, notably among women (RR = 2.4, 95% CI: 1.2 - 4.6) (Bertazzi et al, 2001).

In 1997, the IARC considered results on four highly exposed industrial cohorts; Steenland et al (1999) extended the follow-up period for the largest of these cohorts (5132 chemical workers at 12 US plants) by 6 years. In cohort mortality analyses, diabetes (any mention on the death certificate) showed a negative exposure-response trend.

In an attempt to reconcile disparate results from two key studies on TCDD and diabetes, data from 990 US Air Force veterans (Ranch Hand) and 1275 referents were re-analysed, as were those on a NIOSH population of 267 chemical workers and 227 referents (Steenland et al, 2001b). An increasing trend was found in prevalence of diabetes with increased TCDD exposure in the Ranch Hand population, with excess risk largely confined to the highest 8% of the exposed group (>78 ppt serum TCDD), which had an OR of 3.21 (95% CI 1.81 - 5.72) vs those with <10 ppt TCDD. However, no such positive dose-response was found in the NIOSH chemical worker population i.e. there was little overall evidence that the exposed workers were at higher risk than non-exposed workers of diabetes or abnormal fasting glucose. The reason for the difference in diabetes dose-response trends between the two studies is unknown. Furthermore, Greene and Paustenbach (2002) and Greene et al (2003) argue that, since the estimated LOAEL for diabetes in the NIOSH cohort (6 people with diabetes in the highest exposure group) is over 30-fold greater than the estimated LOAEL in the Ranch Hand cohort, it is “highly unlikely” that TCDD is a significant risk factor for diabetes.

Calvert et al (1999) conducted a cross-sectional study on 281 workers employed more than 15 years earlier in the manufacture of 2,4,5-trichlorophenol or its derivatives at two US chemical plants. Mean current serum lipid adjusted TCDD was 220 pg/g lipid in workers and 7 pg/g lipid among 260 referents. The prevalence of diabetes mellitus was not significantly different between the workers and referents and did not significantly correlate with increasing TCDD concentration. However, diabetes was found in six of 10 (60%) workers with current serum TCDD concentrations >1500 pg/g lipid. Excluding subjects being treated for diabetes, workers in the group with the highest half-life extrapolated TCDD concentrations had a significantly increased adjusted mean serum glucose concentration compared with referents, as well as a significantly higher adjusted mean free thyroxine index. These findings provide modest evidence that TCDD exposure may affect glucose metabolism and thyroid function.

Blood serum lipid concentrations of TCDD in 69 persons living within 25 miles of a Superfund site in the USA (Vertac/Hercules site, Jacksonville, Arkansas) ranged between 2 and 94 ppt. When subjects with TCDD levels in the top 10% (TCDD > 15 ppt, n = 7) were compared to subjects with lower levels (2-15 ppt, n = 62), their plasma insulin concentrations at fasting and 30, 60 and 120 min following a 75 g glucose load were significantly higher. There were no group differences in age, obesity, gender

distribution, total lipids, or glucose levels. Excluding other known risk factors for hyperinsulinaemia, the study authors suggested that high blood TCDD levels might be a factor in insulin resistance (Cranmer et al, 2000).

Longnecker and Michalek (2000) examined the association of serum TCDD with prevalence of diabetes mellitus and with levels of serum insulin and glucose in 1,197 veterans in the US Air Force Health Study who never had contact with dioxin-contaminated herbicides; their serum dioxin levels were within the range of background exposure typically seen in the USA ($\leq$10 ng/kg lipid). Compared with those whose serum dioxin level was in the first quartile (<2.8 ng/kg lipid), the multivariate-adjusted odds of diabetes among those in the highest quartile ($\geq$5.2 ng/kg lipid) was 1.71 (95% CI = 1.00-2.91). The association of background-level dioxin exposure with the prevalence of diabetes in these data may be due to reasons other than causality but a causal contribution cannot be dismissed.

Longnecker and Daniels (2001) noted that rates of both type 1 and type 2 diabetes mellitus have been increasing, with genetic factors accounting for less than half of new cases. For type 1 diabetes, higher serum levels of PCBs have been associated with increased risk but overall, the data were limited or inconsistent. With respect to risk of type 2 diabetes, data were suggestive of an association with TCDD but were inconclusive. Other researchers (eg. Greene et al, 2003; Kogevinas, 2001; Koveginas et al, 2001) have similarly concluded that the evidence for increased risk for diabetes with TCDD exposure is inconsistent.

An analysis by Remillard and Bunce (2002) estimated that background exposure to dioxin-like compounds by the reference population in a number of published epidemiology studies contributed less than 1% of their diabetes risk.

In a survey of Australian Vietnam veterans (self-reporting questionnaire), the reported prevalence of diabetes was a little higher than expected for this population (DVA, 2000). Thus, 2,391 respondents (6%) reported 'diabetes', with the expected general population estimate from the National Health Survey (NHS) being in the range 1,558-2,003 (for the age profile and number of respondents). 'Diabetes' was not defined in the questionnaire and veterans may have included a single high sugar value as diabetes - these conditions are separated in the NHS. The report concluded that a relationship between exposure during service and the disease "is difficult to confirm". This result is perhaps not particularly surprising since it appears that all Australian veterans from the Vietnam war were surveyed i.e. those who might have been more exposed to Agent Orange during Operation Ranch Hand do not appear to have been separately identified. [Current government policy allows for treatment and compensation responses to this condition following diagnosis.]

It may be concluded that there is suggestive evidence of a weak correlation between diabetes incidence and occupational or accidental exposure to dioxins[10]. However,

[10] The issue of whether there could be a reverse correlation does not appear to have been addressed in studies to date ie could diabetics haave different metabolic/physiological characteristics which might alter their capacity to metabolise and/or excrete dioxins or PCBs?

background exposure to dioxins is not a significant risk factor for individuals who have not been occupationally or accidentally exposed.

#### *2.2.2.4 Cardiovascular effects*

In 1997, the IARC considered results on four highly exposed industrial cohorts. Steenland et al (1999) extended the follow-up period for the largest of these cohorts (5132 chemical workers at 12 US plants) by 6 years. In cohort mortality analyses, Standardised Mortality ratios (SMRs) for heart disease showed a weak increasing trend with higher exposure.

Follow-up of the population exposed to dioxin after the 1976 accident in Seveso, Italy, was extended to 1996. Chronic circulatory and respiratory diseases were moderately increased, suggesting a link with accident-related stressors and chemical exposure (Bertazzi et al, 2001).

Between 1965-1968 in the former Czechoslovakia, ca. 80 persons became ill due to occupational exposure to TCDD. Pelclova et al (2002) investigated disorders in a group of 12 of the most highly exposed subjects (mean estimated concentration at the time of exposure approx. 5000 pg/g plasma lipid). The mean TCDD level in 1996 was 256 pg/g plasma lipid (range 14-760). Hyperlipidemia, atherosclerotic plaques, increased intima-media thickness of the carotid artery cf. controls, ischaemic heart disease and degenerative changes of the ocular fundus were very common in the group. TCDD levels correlated with the highest levels of triglycerides and cholesterol found during the 35-year follow-up.

In a study on 1,224 Korean veterans who served in Vietnam and 154 non-Vietnam veterans, Kim et al (2003) reported that "service in Vietnam" resulted in an increased frequency of eczema (odds ratio = 6.54), radiculopathy[11] (OR = 3.98), diabetes (OR = 2.69), peripheral neuropathy (OR = 2.39), and hypertension (OR = 2.29), compared to non-Vietnam veterans, adjusting for potential confounders. Higher exposure to Agent Orange among the Vietnam veterans was claimed to be associated with increased frequency of ischaemic heart disease, valvular heart disease, and retinopathy.

#### *2.2.2.5 Immune system effects*

Studies in animals indicate that the immune system is a sensitive target of TCDD toxicity, with inhibition of immunoglobulin secretion and decreased resistance to bacterial, viral, and parasitic infections. However, information regarding the toxicity of TCDD to the human immune system is scant and inconsistent (ATSDR, 1998; Baccarelli et al, 2002; US EPA, 1994). Natural killer cells were increased in a population of chemical workers exposed to TCDD examined 17 years after termination of exposure (Jennings et al, 1988). A 2-year assessment of two Viennese office workers who had massive exposure to TCDD in 1997, quantitative and functional analysis of the immune system was unrevealing, apart from a decreased percentage of NK cells (Geusau et al, 2001a). Nearly 20 years after the Seveso accident, immunoglobulin and

[11] Nerve root irritation which is caused by either compression of the nerve root where it emanates from the spinal cord area, or from a stretch injury or inflammation of the nerve; can cause a shooting pain sometimes described as an electrical feeling.

complement plasma levels were measured in a random sample of the population in the most highly exposed zones (n = 62) and from surrounding non-contaminated areas (n = 58). Plasma IgG levels decreased with increasing TCDD plasma concentration whereas IgM and IgA immunoglobulins and C3 and C4 complement proteins[12] did not exhibit any consistent association with TCDD levels (Baccarelli et al, 2002). Clinical illness associated with immune system disorders has not been associated with TCDD in any cohort studied (Greene et al, 2003).

#### *2.2.2.6 Endometriosis*

Evidence shows that dioxins can increase the incidence and severity of endometriosis in monkeys and can promote the growth or survival of endometrial tissue implanted into rodents in a surgically induced model of endometriosis. However, small, hospital-based case-control studies have failed to provide compelling evidence for or against an association of environmental contaminants and endometriosis (Rier & Foster, 2002, 2003).

A population-based historical cohort study was conducted 20 years after the 1976 factory explosion in Seveso, Italy, which resulted in the highest known population exposure to TCDD (Eskenazi et al, 2002). Participants were 601 female residents of the Seveso area who were less than 30 years old in 1976 and had adequate stored sera. 19 women with endometriosis and 277 non-diseased women were identified. The relative risk ratios for women with serum TCDD levels of 20-100 ppt and >100 ppt were 1.2 [90% CI = 0.3-4.5] and 2.1 (90% CI = 0.5-8.0), respectively, relative to women with TCDD levels <20 ppt. In conclusion, a doubled but non-significant risk for endometriosis among women with serum TCDD levels of >100 ppt was reported, with no clear dose response.

A case-control study to determine the possible association between endometriosis and chronic exposure to dioxins and PCBs included 42 infertile endometriosis cases and 27 mechanically infertile controls enrolled at one of the US collaborating Centres for Reproductive Medicine between 1996-1998. Results showed no statistically significant association between levels of dioxin-like compounds and the occurrence of endometriosis in infertile women (Pauwels et al, 2001). Tsutsumi et al (2000) have reported that breast-fed infants have an unexpectedly lower incidence of endometriosis in adult life than non breast-fed infants, noting that such females have a possible greater exposure to dioxins in milk.

#### *2.2.2.7 Reproductive and developmental effects*

The majority of studies on human reproductive and developmental effects concern paternal exposure to TCDD, and have evaluated its potential toxicity long after a high exposure had occurred (IARC, 1997). Studies of the risk of spontaneous abortion involving occupational and environmental herbicide exposure have generally not found increased risks (ATSDR, 1998; IARC, 1997; Institute of Medicine, 1994; Sweeney, 1994; US EPA, 1994). Findings from studies of US Vietnam veterans suggested an

[12] Serum complement comprises a group of proteins that facilitate immunological and inflammatory responses. There are 9 major components labelled C1 through C9. The so-called complement cascade involves a series of enzymatic reactions that take place in the blood.

effect with increasing self-reported or inferred Agent Orange exposure (Institute of Medicine, 1994). However, the inconsistency with results of the occupational and environmental exposure studies and the marginal magnitude of the increased risk make these results suspect (Institute of Medicine, 1994). A study of workers in US factories producing Agent Orange did not find an association between paternal serum TCDD levels and the incidence of spontaneous abortion (Schnorr et al, 2001). Most studies of spontaneous abortion have suffered from a high level of misclassification of exposures and outcomes, small sample sizes, lack of data on TCDD levels at the time of conception, and differences in case definition. Similarly, results from human studies of developmental effects and exposure to herbicides or TCDD have, in the main, been inconclusive (ATSDR, 1998; Institute of Medicine, 1994; Sweeney, 1994; US EPA, 1994). The studies have been limited due to small sample sizes (for specific birth defects), potential biases in the findings, and uncertainties regarding the assessment of exposure. Egeland et al (1994) demonstrated that current and half-life serum dioxin levels were positively and significantly related to luteinizing and follicle stimulating hormones and inversely related to testosterone levels in male workers from the NIOSH cohort. Vietnam veterans were found to have a significantly lower sperm concentration relative to non-Vietnam veterans (CDC, 1989). The ability to produce children was not affected, and with the exception of Ranch Hand veterans, the most highly exposed military personnel, Vietnam veterans did not have increased body burdens of TCDD. No associations between TCDD exposure and hormone levels or sperm characteristics were observed among Ranch Hand veterans (Henriksen et al, 1996); however, the investigators noted that the members of this cohort were exposed to lower levels of TCDD and for shorter duration than the workers followed by Egeland et al (1994).

Considerable attention has been paid to the sex ratio of children born to populations exposed to dioxins. Children (346 girls and 328 boys) born between 1977 and 1996 to potentially exposed parents from Seveso, Italy, showing an increased probability of female births with increasing TCDD concentrations in the serum of the fathers ($p = 0.008$). Fathers exposed when they were younger than 19 years of age sired significantly more girls than boys (sex ratio 0.38; 95% CI 0.30-0.47), an effect which may persist for years after exposure. The median concentration of dioxin in fathers in this study was similar to doses that induce epididymal impairments in rats and is about 20 times the estimated average concentration of TCDD currently found in human beings in industrialised countries (Mocarelli et al, 2000). The sex ratios of live births in Japan after accidental exposure to PCBs and PCDFs in 1968 were reviewed (Yoshimura et al, 2001). Data on all births (85 live) from parents exposed from 1968 to 1977 in Fukuoka and a region of Nagasaki, were examined. The sex ratio was not significantly different from normal (0.513). However, the authors noted that further investigation, especially of offspring of those who were younger than about 19 years of age at the time of the Yusho incident, is warranted. Men who worked in US factories which produced Agent Orange were exposed to TCDD at levels hundreds of times higher than TCDD levels in the general population. Wives of TCDD-exposed chemical workers and wives of non-exposed neighbourhood referents were interviewed to determine reproductive history while paternal serum TCDD level at time of conception was estimated for each pregnancy, using serum samples taken in 1987. Although estimated TCDD levels in the exposed worker population were much higher than in other studies, this study (Schnorr et al, 2001) did not find an association between paternal serum TCDD levels and the sex

ratio of offspring. The sex ratio of children of pesticide workers who produced trichlorophenol and 2,4,5-trichlorophenoxy acetic acid from 1961 to 1988 in the city of Ufa, Bashkortostan, Russia was investigated. TCDD and other dioxins were analysed in 84 blood samples, with median TCDD toxic equivalents blood lipid values of 240 ng/kg i.e. more than 30 times higher than background levels from the region. The sex ratio in the combined cohort of 227 children from exposed workers (150 males and 48 females) was 0.40 (M/M+F), significantly lower than those for the city of Ufa and elsewhere, while the sex ratio of offspring according to maternal or paternal exposure was 0.38 and 0.51 respectively. Thus, paternal exposure was associated with the birth of more girls in this study (Ryan et al, 2002).

A recent Russian paper reports on adverse reproductive outcomes in the town of Chapaevsk (Samara Region, Russia), home to the Middle Volga chemical plant which is one of the largest environmental polluters in region. From 1967 to 1987 it produced lindane (hexachlorocyclohexane) and its derivatives. The mean frequency of spontaneous abortions for a recent seven-year period was 24.4% higher in Chapaevsk than in other towns in the Samara region. The average rate of premature labour was also significantly higher, at 45.7 per 1000 women. The frequency of newborns with low birth weight was 7.4%, slightly (but not statistically) higher than the 5.1-6.2% for Russia and most other Samara region towns. The numbers of congenital morphogenetic conditions (CMGC) were determined in 369 children born between 1990 and 1995. The average number of CMGC per child was claimed to be significantly higher than in other parts of the region. These preliminary results indicate adverse reproductive outcomes which, although the town suffers from pollution with a range of different chemicals, the authors associate with high dioxin levels in human milk and blood (Revich et al, 2001).

NIOSH scientists studied pregnancy outcomes of wives of chemical workers exposed to chemicals contaminated with TCDD. Their findings did not support any relationship between paternal TCDD exposure and spontaneous abortion or sex ratio of offspring (Schnorr et al, 2001) or lowered birth weight or pre-term delivery (Lawson et al, 2004).

#### *2.2.2.8 Neurological and developmental cognitive effects*

Neurological symptoms observed in TCDD-exposed workers include lassitude, weakness of the lower limbs, muscular pains, increased perspiration, loss of appetite, headaches, nervousness, anxiety, irritability, and loss of libido (Ashe & Suskind, 1950; Jirasek et al, 1974, 1976; Moses et al, 1984; Oliver, 1975; Pazderova-Vejlupkova et al, 1981; Suskind, 1985). In Japanese Yusho patients who ingested rice oil containing PCBs and PCDFs in 1968, some still complain of numbness of extremities (Yoshimura, 2003). Clinical and neurophysiological examinations (motor conduction velocity of the peroneal nerve, sensory conduction velocities of the sural and ulnar nerves) on 156 dioxin exposed workers (42 with, 114 without chloracne) from a pesticide-producing plant found that exposure to 2,3,7,8-polychlorinated dioxins and furans led to mild sensory neuropathy of the legs in a minority of the most severely exposed persons (Thomke et al, 1999). In veterans of Operation Ranch Hand, the unit responsible for aerial herbicide spraying in Vietnam from 1962 to 1971, there was an increased risk of indices of peripheral neuropathy in the high-exposure group at assessment in 1992 and 1997; however, the authors urged caution in interpretation of these findings until the relationship between pre-clinical diabetes mellitus and peripheral neuropathy is further

evaluated (Michalek et al, 2001). Also in veterans of Operation Ranch Hand, an analysis of cognitive function (performed in 1982) found that veterans in the fifth quintile of dioxin levels (measured in 1987 and 1992) exhibited reduced verbal memory function; although statistically significant, these differences were relatively small and of uncertain clinical significance (Barrett et al, 2001).

For children exposed *in utero*, postulated adverse health effects include subtle developmental delays and thyroid hormone alterations. Much of the focus of recent research has been on the effect of prenatal PCB exposure on cognitive and neurological development. The potential neurotoxicity of PCBs was first recognized when people in Japan (1968) and Taiwan (1978-1979) consumed rice oil contaminated with PCBs and PCDFs; offspring had poorer cognitive functioning as well as other behavioural problems. Taiwanese 'Yu-Cheng' children born up to 6 years after their mother was exposed were as affected as children born within the first year, when compared at the same ages; effects on IQ persisted up to 16 years of age, but behavioural problems diminished with time (Lai et al, 2001; Liu et al, 2001). Further studies, including on children whose mothers consumed PCB-contaminated Great Lakes fish, have produced discrepant results. Recent Dutch research reported a negative relationship between prenatal PCB exposure and intellectual functioning at 3.5 years of age, without any relationship between intellectual functioning and exposure to dioxins and dibenzofurans. Additional studies are being conducted in Europe and North America (Schantz, 2001).

In the Netherlands a prospective study was started in 1989 to investigate the effects of background PCB and dioxin exposure on the development of healthy babies born at normal term. Prenatal PCB exposure was related to lower psychomotor scores at 7 months of age, and poorer neurological condition at birth and at 18 months. Postnatal PCB and dioxin exposure through lactation was related to lower psychomotor development at 7 months (Vreugdenhil & Weisglas-Kuperus, 2000). In a follow-up of the Dutch PCB/Dioxin study, cognitive abilities were assessed in 42-month-old children. *In utero* exposure to "background" PCB concentrations was reported to be associated with poorer cognitive functioning in preschool children. Children of mothers at the upper end of exposure were at greater risk (Patandin et al, 1999a). Whilst findings suggested that prenatal exposure to PCBs and dioxins might have subtle negative effects on early neurological and cognitive development of children, a consistently beneficial effect of breast-feeding on brain development from 18 months up to school age was reported, despite a higher PCB exposure from breast milk. However, by 6 years of age, preliminary results showed no evidence that cognitive and neurological development were affected by pre- and postnatal exposure to these pollutants (Boersma et al, 2001). In the Dutch PCB/dioxin study, the assessment of school-age children suggested that subtle cognitive and motor developmental delays arising from prenatal PCB and dioxin exposure was seen when parental and home characteristics were less optimal but such effects were not measurable in children raised in more optimal environments (Vreugdenhil et al, 2002a).

In the US Collaborative Perinatal Project (CPP), designed to identify determinants of neurological deficits in children, prenatal PCB exposure in relation to children's cognitive test scores was studied. Pregnant women were recruited from 12 US study

centres from 1959 to 1966, and the children were followed until age seven. Third-trimester serum from 806 women selected at random and from an additional 96 women whose children had either a low or high IQ score was analysed for 11 specific PCBs. The data provided no support for the hypothesis that *in utero* exposure to background levels of PCBs was associated with lower IQ scores at age seven (Gray et al, 2000). Silkworth et al (2002) applied causation analysis to 24 epidemiology studies (on 2,573 children in 6 international cohorts) that sought an association between maternal PCB exposure and neurodevelopmental effects. The authors concluded that although there is biological plausibility, a causal association between the ascribed cause (PCBs) and the purported effect (impaired neurodevelopment) was without empirical support. Performance of more highly PCB-exposed breast-fed children was not diminished, but was positively correlated with duration of breast-feeding. Some negative correlations reported between neurodevelopment and PCBs were equally attributable to lead or mercury.

#### *2.2.2.9 Tooth Development*

*In vivo* and *in vitro* studies show that rat and mouse teeth are sensitive to TCDD throughout their development (eg. Kattainen et al, 2001; Lukinmaa et al, 2001; Partanen et al, 2004). The sequence of morphogenetic events can be affected, leading to failure of tooth germs to develop as a result of accelerated and increased apoptosis in the dental lamina connecting the oral epithelium and the tooth germ. Later exposure can reduce tooth size or, in more advanced teeth, root development can be arrested (Lukinmaa et al, 2001). TCDD can also affect the function of secretory ameloblasts and odontoblasts, resulting in delayed or defective mineralization of the molar teeth and failure of enamel and dentin formation to be completed in the continuously erupting rat incisors (Lukinmaa et al, 2001 and references therein).

In two episodes of epidemic poisoning in Japan and Taiwan (so-called Yusho and Yu-Cheng incidents, respectively), developmental effects were observed in infants and children born to mothers who had been exposed to PCDFs and PCBs (see eg. Yoshimura, 2003; Rogan et al, 1988). These included a higher incidence of natal teeth[13] and later, missing permanent teeth, delayed eruption of permanent teeth, and disturbed root development (Ikeda, 1996; Rogan et al, 1988).

Twenty-five years after the dioxin accident in Seveso, Italy, 48 subjects exposed in their childhood in more (zones A and B) or less contaminated (zone R) areas were randomly recruited for examination of dental and oral aberrations (Alaluusua et al, 2004). Subjects were matched with 65 subjects from the surrounding non-ABR zone for age, sex, and education. The prevalence of developmental enamel defects in group less than 5 years of age at the time of exposure was 42% (15/36) in zone ABR subjects and 26% (10/39) in non-ABR subjects, correlating with serum TCDD levels ($p = 0.016$). Hypodontia[14] was seen in 12.5% (6/48) and 4.6% (3/65) of zone ABR and non-ABR subjects, respectively, also correlating with serum TCDD level ($p = 0.05$). In contrast, dental caries and periodontal disease (both due to infections), oral pigmentation and salivary

[13] Natal teeth are teeth present at birth and neonatal teeth erupt during the first 30 days. Normally the lower central incisors are the first teeth to erupt at approximately 6 months of age.
[14] Congenital absence of one or more teeth.

flow rate were unrelated to exposure. Whilst the authors commented that the results supported their hypothesis that dioxins can cause dental aberrations, they noted that (1) almost one hundred different factors can affect development of dental enamel (citing Small & Murray, 1978) and (2) the results on hypodontia should be treated with caution because of the small study population and the small number with hypodontia, and that a larger study on children under 3 at the time of the accident (the most critical age for tooth agenesis) should be conducted.

A Finnish study (Alaluusua et al, 1996) looked at 2 different populations of children; the first population comprised 40 children who had mineralization defects in the permanent 1st molars, and their age, living area, and sex-matched controls. The median duration of breast feeding was 9 months in the affected children compared to 6 months in the controls. The defects were more extensive after prolonged breast feeding. The second population consisted of 97 children whose mothers had been encouraged to extensive and prolonged breast feeding (>8 months). Of these children, 24 had mineralization defects. In both populations, mineralization defects were associated with the duration of breast feeding. The result led to the conclusion that long breast feeding may increase the risk of mineralization defects in children, possibly because of environmental contaminants (not identified in this study). In a later study, Alaluusua et al (1999) examined the dentition of 102 children aged 6-7 years for the presence of hypomineralisation enamel defects, in order to correlate any effects on the permanent first molars with concentrations of the most toxic PCDDs/PCDFs and 33 PCB congeners in breast milk samples collected when the children were aged 4 weeks. Exposure was evaluated from the duration of breastfeeding (mean 10.5 months) and the concentrations in milk (assuming a yearly 25% first-order decline during lactation). Intrauterine exposure was estimated to correspond to the exposure *via* milk for two months. Mineralisation defects occurred more often and were more severe in children who had been exposed to higher amounts of polychlorinated aromatic hydrocarbons than in those exposed to lower amounts.

Holtta et al (2001) examined the prevalence of demarcated hypomineralization lesions of teeth in 2 Finnish towns by the Kymijoki River which is severely contaminated by dioxins and furans. The 4,120 permanent first molars of 1,030 children were studied and the prevailing levels of dioxins and furans in human milk were measured. Neither the prevalence of dental lesions nor the levels of PCDD/Fs in human milk were increased in riverside residents compared with figures reported earlier from other areas of Finland. The prevalence of the defects in Kotka and Anjalankoski was 14.2% and 5.6% respectively, with corresponding PCDD/F levels in breast milk of 13.4 and 10.9 I-TEQ pg/g fat. Higher levels of fluoride in the second town may have lowered the prevalence of demarcated lesions ie. it is not valid to draw correlations between the prevalence of the defects and the difference (relatively minor) in exposures to PCDD/F levels. Only in Anjalankoski was the duration of breast-feeding associated with the prevalence of the defects.

A total of 34,457 infants born in 1997-2000 in four hospitals in southern Finland were examined for natal and neonatal teeth (Alaluusua et al, 2002). Exposures to PCBs and PCDD/Fs was evaluated by measuring the 17 most toxic PCDD/Fs and 36 PCB congeners in breast milk samples when the children were 4-8 wks old. A total of 34

infants had one or two natal (29 infants) or neonatal teeth (5 infants). The milk analyses showed that the median level of PCDD/Fs was 11.9 WHO-TEQ pg/g in fat, and that of PCBs was 7.24 WHO-TEQ pg/g in fat ie. levels corresponded to the prevailing levels in Norway at the time. No association was found between pollutant levels and occurrence of natal and neonatal teeth, indicating that the prevailing levels of PCDD/Fs and PCBs are likely to be below the threshold to cause perinatal eruption of teeth.

*2.2.2.10 Cancer*

In 1997, the IARC considered results on four highly exposed industrial cohorts; Steenland et al (1999) extended the follow-up period for the largest of these cohorts (5132 chemical workers at 12 US plants) by 6 years. The SMR for all cancers combined was 1.13 (95% CI = 1.02-1.25), with statistically-significant positive linear trends in SMRs with increasing exposure for all cancers combined and for lung cancer. The SMR for all cancers combined for the highest exposure group was 1.60 (95% CI = 1.15-1.82). Analyses suggest that high TCDD exposure resulted in an excess of all cancers combined, without any marked specificity. However, excess cancer was limited to the highest exposed workers, with exposures that were likely to have been 100-1000 times higher than those experienced by the general population. Based on the data from the US NIOSH cohort of workers exposed to dioxin, Steenland and co-workers (Steenland et al, 2001a; Steenland & Deddens, 2003) estimated that doubling background levels of exposure (eg. by eating a significant amount of dioxin-contaminated fish) could increase lifetime risk of cancer death by ca. 0.1 to 1.0%; since the background risk of cancer death by age 75 is 12% in the USA, doubling background levels of dioxin exposure would increase this lifetime risk to somewhere between 12.1 and 13.0%.

Salvan et al (2001) performed an analysis of all cancer and lung cancer mortality in relation to estimated absorbed dose of TCDD in the NIOSH cohort of chemical workers. At a dose level of 100 times the background, their estimates obtained with a 10-year lag translated into a relative risk of 2.03 (95% CI =1.19-3.45) for all cancer and of 2.66 (95% CI = 1.07-6.64) for lung cancer.

Follow-up of the population exposed to dioxin after the 1976 accident in Seveso, Italy, was extended to 1996. During the entire observation period, all-cause and all-cancer mortality did not increase. Fifteen years after the accident, mortality among men in high-exposure zones A (804 inhabitants) and B (5,941 inhabitants) increased from all cancers (RR = 1.3, 95% CI = 1.0-1.7), rectal cancer (RR = 2.4, 95% CI = 1.2-4.6), and lung cancer (RR = 1.3, 95% CI = 1.0-1.7), with no latency-related pattern for rectal or lung cancer. An excess of lympho-haemopoietic neoplasms was found in both genders (RR = 1.7, 95% CI = 1.2-2.5). Hodgkin's disease risk was elevated in the first 10-year observation period (RR = 4.9, 95% CI: 1.5, 16.4), whereas the highest increase for non-Hodgkin's lymphoma (RR = 2.8, 95% CI = 1.1-7.0) and myeloid leukemia (RR = 3.8, 95% CI = 1.2-12.5) occurred after 15 years. No soft tissue sarcoma cases were found in these zones (0.8 expected) (Bertazzi et al, 2001).

Using data from the Seveso Women's Health Study (SWHS), Warner et al (2002) examined the association between individual serum TCDD levels and breast cancer risk. The cohort comprised 981 women who were infants to 40 years old at the time of the factory explosion in 1976, who resided in the most contaminated areas, and had

archived sera that was collected soon after the explosion. Cox proportional hazards modelling showed that the hazard ratio for breast cancer associated with a 10-fold increase in serum TCDD levels was significantly increased to 2.1 (95% CI = 1.0-4.6), leading to the conclusion that individual serum TCDD is significantly related with breast cancer incidence among women in the SWHS cohort.

Epidemiological evidence from the most highly TCDD-exposed cohorts studied produces the strongest evidence of an increased cancer risk from exposure to dioxins, when the data are considered for all cancers combined. There is weaker evidence of an increased cancer risk when the data for cancers at particular sites are considered.

It is difficult to find epidemiological data that have sufficient dose-response information to provide reliable risk estimates in exposed human populations. Modelling is complicated by uncertainties in extrapolating current body burdens of dioxins to past occupational exposure and by the choice of the dose-response model to fit the data. Scientific debate about the potential human carcinogenicity of dioxin-like compounds has been ongoing for many years and recent meta-analyses (US EPA, 2000; Starr, 2001; Crump et al, 2003) from three occupationally-exposed cohorts have reached such different conclusions that the debate is certain to continue. While the potency estimate from the US EPA's analysis was stated to imply approximately 4,000 additional cancer deaths in the USA solely from background intake of dioxin-like compounds (about 1 pg TEQ/kg/day), Thomas Starr's own analysis implied zero extra cancers from all exposures to dioxin-like compounds, including those arising from dietary intake (Starr, 2003). Crump et al (2003) concluded that their analysis provided "some evidence that TEQ exposures near current background levels are carcinogenic". Further consideration of the issue by Starr (Starr, 2003) indicated that resolution of the debate would depend on detailed information about exposures to TCDD and direct-acting carcinogens in the workplace, as well as a model which adequately takes into account TCDD's characteristics as a tumour promoter. Starr was also strongly critical of extrapolations from TCDD analyses to ones based on TEQ, stating that "the evidence regarding the potential carcinogenicity of TEQ is simply inadequate".

Mackie et al (2003) have commented on the US EPA's standard low-dose linear extrapolation method for estimating dioxin cancer risk (US EPA, 2000) and the subsequent consideration by the EPA's Science Advisory Board (SAB) (US EPA, 2001a). As an alternative to the linear extrapolation model, the SAB considered a model which suggested that dioxin was a threshold carcinogen, with data suggesting that the threshold was an order of magnitude higher than exposure levels of the general population. A re-analysis of this model by Mackie et al indicates that without the inappropriate population weighting in the model considered by the SAB, the range of possible estimated thresholds is extremely wide and completely overlaps the level of general US background exposures, with the conclusion that there is no evidence for or against the proposition that dioxin is a threshold carcinogen. More standard statistical approaches (Steenland et al, 2001b; Becher et al, 1998) found no evidence of a threshold.

Yamaguchi (1999) has cautioned against relying on estimates of absolute risk from epidemiological studies in human populations, noting that estimates of cancer risk

arising from exposure to chemicals varied very significantly between eg. smokers and non-smokers.

As noted above under 'Animal data', the background incidence of certain tumours is reduced in rodents by TCDD. In this regard, Kayajanian (2002) has suggested that the NIOSH study on exposed chemical plant workers indicates a J-shaped response, with increased cancer incidence at higher exposures being preceded at lower doses by a significantly reduced incidence. Kayajanian (1999) used plant-worker mortality data which underlie the 1990 US National Institute for Occupational Safety and Health (NIOSH) report on dioxins to identify tissue/organ sites at which dioxin exposure is associated with, reductions in mortality. Observations in men included reductions in urinary organ cancers, including bladder cancers; multiple myeloma; respiratory diseases, including emphysema and pneumoconioses and other respiratory diseases; total disease other than cancer; and total disease.

Ketchum et al (1999) studied cancer prevalence and exposure to TCDD in veterans of Operation Ranch Hand, the Air Force unit responsible for the aerial spraying of herbicides in Vietnam from 1962 to 1971. The risk of cancer at sites other than the skin within 20 years of service was increased in the low (odds ratio [OR] = 3.4, 95% CI = 1.5-8.0) and high (OR 2.7, 95% CI = 0.9-8.0) TCDD exposure categories, but the pattern was inconsistent with another study, suggesting that the excess risk may not have been caused by dioxin exposure. Overall, there was no consistent evidence of a dose-response gradient and no significant increase in cancer risk in the high dioxin exposure category, the subgroup of greatest *a priori* interest.

Kayajanian's analysis of Operation Ranch Hand data (Kayajanian, 2000) suggested that significant increases in systemic, melanoma, and total skin cancers are observed in those veterans not significantly exposed to dioxin; however, amongst those Ranch Hand airmen who served in Southeast Asia, exposure to dioxins is associated with a significant reduction of elevated systemic cancers and total skin cancers. In the Operation Ranch Hand Study, a significant reduction in prostate cancers as a function of increasing dioxin body burden was reported in US veterans of African origin but not in Caucasians (Kayajanian, 2001). Zafar and Terris (2001) also evaluated the rate of prostate cancer in Vietnam veterans. Those referred for prostate biopsy who reported a history of Agent Orange exposure were compared to veterans who denied such exposure; there was no evidence of a relationship between prostate cancer incidence and Agent Orange exposure.

The Australian Government Department of Veterans' Affairs conducted a mortality study on Vietnam veterans (the "Vietnam Veterans Mortality Study") covering the period from the end of the Vietnam War until 31 December 1994 (Crane et al, 1997). The death rate from all causes for Vietnam veterans relative to other Australian males was estimated to be 0.68 (95% CI 0.63 to 0.74) for 1964-79 and 1.07 (95% CI 1.02 to 1.12) for 1980-94; these estimated SMRs take account of the known variation in death rates by age group and calendar year. The overall level of excess mortality was difficult to estimate because of the 'healthy worker effect' which would lower the death rates for some causes, and the bias in the estimation method due to the underestimation of deaths. Compared with deaths from other sites of cancer, death rates from soft tissue and other

sarcomas, non-Hodgkin's lymphoma, and Hodgkin's disease, which were suggested as being consistently associated with exposure to herbicides or dioxin, were not statistically significantly elevated. This study suggests there may be a slight excess risk of death from lung cancer and prostate cancer. The report authors noted that while this elevation may be related to some exposure that occurred during service in Vietnam, there are multiple other and more usual risk factors associated with both cancers that should also be considered. Although not hypothesised in the protocol for this study, Vietnam veterans may have been at increased risk of death from head and neck cancers between 1980-94.

## 2.3 Recent Assessments of Dioxins

Comprehensive risk assessments of dioxins have been performed by a number of organisations or groups in recent years including the International Agency for Research on Cancer (IARC), the US EPA, the EC Scientific Committee on Food (EC-SCF), the WHO European Centre for Environmental Health (WHO-ECEH) and the Joint Expert Committee on Food Additives (JECFA). These assessments incorporate knowledge from research on molecular biology, animal toxicity and epidemiology in exposed human populations.

### 2.3.1 Assessment by the International Agency for Research on Cancer

In 1997, the IARC classified TCDD as 'carcinogenic to humans' (Group 1). The IARC's decision was based primarily on evidence in four groups of highly-exposed industrial workers. IARC also took into consideration the following supporting evidence:

- there was 'sufficient evidence'[15] that TCDD was carcinogenic at several sites in experimental animals (acting *via* the cellular aryl hydrocarbon (*Ah*) receptor, which is present in and functions the same way in humans and laboratory species);
- there were studies showing that the concentrations of TCDD in tissues from rats exposed to carcinogenic dosage regimens in bioassays are similar to those found in the tissues of heavily-exposed human populations with an apparent increased risk of cancer (IARC, 1997).

Taking all of the evidence into consideration, the following overall evaluations were made by IARC (1997):

- 2,3,7,8-Tetrachlorodibenzo-*p*-dioxin (TCDD) is carcinogenic to humans (Group 1).

[15] IARC usually applies the criterion of 'sufficient evidence of carcinogenicity' when a causal relationship has been established between the agent or mixture and an increased incidence of malignant neoplasms or an appropriate combination of benign and malignant neoplasms in (a) two or more species of animals or (b) in two or more independent studies in one species carried out at different times or in different laboratories or under different protocols.

- Other polychlorinated dibenzo-*p*-dioxins are not classifiable as to their carcinogenicity to humans (Group 3).
- Dibenzo-*p*-dioxin is not classifiable as to its carcinogenicity to humans (Group 3).
- Polychlorinated dibenzofurans are not classifiable as to their carcinogenicity to humans (Group 3).

The IARC noted that in these high-exposure industrial cohorts, the blood lipid levels estimated to the last time of exposure were 2000 ng/kg (mean, with levels up to 32,000 ng/kg; US cohort), 1434 ng/kg (geometric mean, range 301 - 3,683 ng/kg; Dutch cohort), 1008 ng/kg (geometric mean; German workers with severe chloracne), and up to 2252 ng/kg (Boehringer cohort, Germany). These calculated blood levels of TCDD at the time of exposure were in the same range as the estimated blood levels in the two-year rat carcinogenicity study (Kociba et al, 197; see assessment above). In rats exposed to 100 ng/kg bw/day in the diet (hepatocellular carcinomas (females) and squamous cell carcinomas of the lung (females), estimated blood lipid TCDD levels were 5,000 - 10,000 ng/kg TCDD. At 10 ng/kg bw/day (the NOEL for hepatocellular carcinomas, but with an increased incidence of hepatocellular nodules), estimated blood lipid TCDD levels were 1,500 -2,000 ng/kg TCDD. At the lowest dose (1 ng/kg bw/day) at which no toxicological effects were reported, the mean blood lipid TCDD level was 540 ng/kg. Thus, the workers in the industrial cohorts studied were likely to have been exposed to TCDD levels similar to those in the experimental animal studies, levels which were 100–1000 times higher than those experienced by the general population.

### 2.3.2 Assessment by the ATSDR

While the Agency for Toxic Substances and Disease Registry (ATSDR) of the Public Health Service of the US Department of Health and Human Services is not an 'international' organisation, its 1998 review of dioxins is one of the most comprehensive reviews of the subject produced to date.

The ATSDR (1998) estimated a Minimal Risk Level (MRL)[16] of 1 pg TEQ/kg bw/day for chronic oral exposure to TCDD, based on developmental toxicity in monkeys (Schantz et al, 1992). This study is presented in more detail under 'Animal data' (see above). Relative to controls, significant alterations in play behaviour, displacement, and self-directed behaviour were observed in offspring of dams exposed to 5 ppt TCDD in the diet, corresponding to a daily intake of 120 pg/kg bw. Offspring behaviour was studied from 8.6 months of age for a period of 9 weeks. An uncertainty factor of 90 was used (3 for the use of a marginal LOAEL, 3 for extrapolation from animals to humans, and 10 for human variability) to derive the MRL. (Note that body burden was not used

[16] Minimal Risk Level (MRL): An estimate of daily human exposure to a hazardous substance that is likely to be without an appreciable risk of adverse non-cancer health effects over a specified route and duration of exposure. MRLs are derived using the NOAEL/LOAEL plus safety factor approach. MRLs established by the ATSDR are generally based on the most sensitive endpoint considered to be of relevance to humans. This should not be confused with Maximum Residue Limit, a control level for pesticide residues in agricultural commodities.

to scale across species in the derivation of the MRL, as compared to eg. the WHO derivation of the TDI.)

The ATSDR also derived an MRL of 0.0002 µg/kg/day (200 pg/kg/day) for acute-duration oral exposure (14 days or less) to TCDD, based on a NOAEL of 5 ng/kg and a LOAEL of 10 ng/kg for immunological effects in female B6C3F1 mice (Burleson et al, 1996); statistically significant increases in mortality were observed in influenza A infected mice exposed to 10, 50 and 100 ng/kg TCDD. An uncertainty factor of 30 (3 for extrapolation from animals to humans and 10 for human variability) and modifying factor of 0.7 (to account for the higher bioavailability of TCDD from an oil gavage vehicle than from food) were used to derive the MRL from the NOAEL. Similarly, an MRL of 0.00002 µg/kg/day (20 pg/kg/day) was derived for intermediate-duration oral exposure (15–364 days) to TCDD, based on a NOAEL of 0.7 ng/kg/day for immunological effects (decreased thymus weights) in Hartley guinea pigs fed TCDD in the diet for 90 days (DeCaprio et al, 1986). The LOAEL for this effect was 5 ng/kg/day. An uncertainty factor of 30 (3 for interspecies extrapolation and 10 for human variability) was used.

The ATSDR concluded that the available epidemiology data suggest that 2,3,7,8-TCDD may be a human carcinogen. Statistically significant increases in risks for all cancers were found in highly exposed workers with longer latency periods. Although the estimated SMRs were low, they were consistent across studies with the highest exposures. The evidence for site-specific cancers is weaker, with some data suggesting a possible relationship between soft-tissue sarcoma, non-Hodgkin's lymphoma, or respiratory cancer with 2,3,7,8-TCDD exposure. The ATSDR emphasised that some of the human studies did not provide adequate exposure data and were confounded by concomitant exposure to other chemicals.

### 2.3.3 Re-assessment by the US EPA

In April 1991, the US EPA announced that it would conduct a scientific re-assessment of the potential risks posed by exposure to dioxins and related compounds, as a follow-up to their initial assessment, first released as a draft in 1984 (US EPA, 1984a).

The principal finding of their draft re-assessment (US EPA, 2000) was that although dioxins can initiate biochemical and biological events potentially leading to a range of cancer types and non-cancer effects in animals and humans, *'there is currently no clear indication of increased disease in the general population attributable to dioxin-like compounds*'. However, the US EPA stated that the lack of a clear indication of disease could not be taken as evidence that dioxins were having no effect. The report suggested that current data and scientific tools might not be able to detect effects. The EPA did not recommend a reference dose[17] (RfD) for dioxins, reasoning that any RfD estimated using the traditional approach for setting such values, would probably be 100–1000 times below current human intakes and body burdens. Hence, the EPA review did not

[17] An RfD is a health risk goal below which there is likely to be no appreciable risk of non-cancer effects over a lifetime of exposure. The RfD concept is ostensibly equivalent to an acceptable daily intake (ADI) or tolerable daily intake (TDI).

produce an exposure standard for humans that could be considered for adoption by Australia.

In 2000/2001 the Science Advisory Board panel reviewing the draft questioned the EPA's quantitative cancer risk estimates, stating that it was not appropriate for EPA to characterise the risks in such a quantitative manner without providing a similar quantitative estimate of the uncertainty in the risk estimates; the Board was not able to reach consensus on a single value for a dioxin cancer potency factor. The panel also considered that it would be useful to have estimates of non-cancer risk from low-dose exposures, but accepted that the database currently did not allow for such estimates to be reliably developed at present (Paustenbach, 2002). It is interesting to note that the majority of the SAB panel recommended that an RfD should be derived, stating that the non-cancer hazard appeared to be the most sensitive adverse effect, rather than the cancer hazard. [A summary of the 2001 Science Advisory Board report is given in Paustenbach (2002).]

As at the time of preparing this hazard assessment overview, the US EPA is yet to release its final risk assessment on dioxins. The US EPA's Science Advisory Board's (SAB) Dioxin Reassessment Review Subcommittee (DRRS) of the SAB Executive Committee met between November 2000 and April 2001 to review sections of the EPA draft EPA document. The DRRS considered that, notwithstanding the fact that it was critical for the EPA to carefully consider current data and modelling gaps and to develop a research plan to remedy them, additional research was unlikely to bridge many of these gaps in the foreseeable future. Therefore it recommended that the EPA proceed expeditiously to complete and release its risk assessment, taking appropriate note of the findings and recommendations of the DRRS report and other public comments. Further, recognising the very long biological and environmental persistence of dioxins, the DRRS stated that it was important that EPA continue to try to limit emissions (and human exposure) to this class of chemicals. On 31 May 2001 the SAB forwarded its final review report to the EPA. A revised draft dioxin reassessment was then transmitted to the Interagency Working Group on Dioxin (IWG) on 17 January 2003; the IWG is made up of American government agencies responsible for human health, food, and the environment and which are working together under the auspices of the National Science and Technology Council to ensure a coordinated government approach to dioxin related issues. On 29 October 2003 the IWG officially requested that the National Academy of Sciences (NAS) re-review the draft dioxin reassessment. This NAS review is expected to take approximately 15 months[18].

### 2.3.4 Assessment by the WHO-ECEH Consultation (1998)

The WHO European Centre for Environmental Health (WHO-ECEH) has been coordinating a program on dioxins, in collaboration with the IPCS. The program is aimed at evaluating the possible health risks, and prevention and control of environmental exposure of the general population to these chemicals. WHO-ECEH and IPCS jointly organised a consultation entitled *Assessment of the health risk of dioxins: re-evaluation of the Tolerable Daily Intake (TDI)*. The meeting was held in May 1998

[18] The EPA plans to make available on its website the version of the dioxin reassessment that is undergoing NAS review.

in Geneva, and was attended by 40 experts from Australia[19], Belgium, Canada, Denmark, Finland, Germany, Italy, Japan, The Netherlands, New Zealand, Spain, Sweden, the United Kingdom and the United States (WHO, 1998; Van Leeuwen et al, 2000).

#### *2.3.4.1 Conclusions from the WHO Consultation*

In assessing the risk from dioxin-like compounds, the consultation focused on the most sensitive adverse effects (hormonal, reproductive and developmental effects) that are observed at low doses in animal studies. These effects occur at body burdens in rats and monkeys in the range of 10–50 ng/kg bw.

Human daily intakes that would lead to body burdens similar to those associated with adverse effects in animals were estimated to be in the range of 10-40 pg/kg bw/day. Since body burdens were used to scale doses across species, the consultation concluded that it was not necessary to use an uncertainty factor to account for toxicokinetic differences between species. However, the estimated human intake was based on LOELs and not on NOELs. In addition, uncertainty remains regarding potential differences in susceptibilities within the human population, the comparative susceptibility of humans and animals, and the half-lives of elimination for the different components of a mixture of dioxins and PCBs vary significantly. To account for these uncertainties, the consultation recommended a composite uncertainty factor of 10.

Based on the range of estimated daily human intakes (10-40 pg/kg bw) that would lead to body burdens similar to those associated with the most sensitive adverse effects in animal studies, and applying an uncertainty factor of 10, a TDI range of 1-4 pg TEQs/kg body weight was established.

The consultation recognised that subtle adverse effects might already be occurring in the general population in some countries at current background levels of exposure to dioxins and dioxin-like compounds. Therefore, it recommended that every effort should be made to reduce exposure to the lower end of this range.

### 2.3.5 Assessment by the EC-SCF meeting (2001)

The EC-SCF is responsible for advising the EC on scientific and technical questions concerning the safety of food, and its advice is used as a basis for EC rules on consumer health and food safety, toxicology and hygiene in the food production chain. In 2000 and 2001, the EC Scientific Committee on Food (EC-SCF) also assessed the risk of dioxins (EC Scientific Committee on Food, 2000; 2001). It used as its starting point the WHO 1998 evaluation (see Section 2.3.4).

#### *2.3.5.1 Conclusions from the EC-SCF*

The EC-SCF based their updated risk assessment on the LOEL for reproductive toxicity in male offspring of pregnant rats from the study by Faqi et al (1998), rather than the rat and monkey studies used by the WHO. An estimated human daily intake (EHDI) of 20

[19] The Australian participant was Professor Michael Moore, National Research Centre for Environmental Toxicology (NRCET), Brisbane.

pg/kg bw/d was calculated from the estimated steady state TCDD body burden in the rat dams at the LOEL of 25 ng/kg bw. When choosing an appropriate safety factor for deriving a TDI, an uncertainty factor accounting for interspecies variation was not considered necessary because the NOEL and LOEL were expressed in terms of body burden, thereby scaling doses from animals to humans. The committee also concluded that no uncertainty factor was required to account for differences within or between species in toxicodynamics (eg. *Ah* receptor binding affinity and enzyme induction). The ultimate safety factor consisted of an uncertainty factor of 3.2 to account for variation between individuals in human toxicokinetics (i.e. differences in absorption, accumulation, metabolism and excretion), and an additional factor of 3 because a LOEL rather than a NOEL was used. Thus, the safety factor was 9.6 (i.e. $3 \times 3.2$). Application of this 9.6-fold safety factor to the EHDI of 20 pg/kg bw yielded a TDI of 2 pg/kg bw/day. Due to the long half-lives of TCDD and related compounds in the human body, this figure was converted to a TWI of 14 pg/kg bw. In order to extend this TWI to include all 2,3,7,8-substituted PCDDs and PCDFs and the dioxin-like PCBs, the EC-SCF established a group TWI of 14 pg WHO TEQs/kg bw for these compounds.

The EC-SCF stressed that:

> *'given the average dietary intakes of dioxins and dioxin-like PCBs in the European countries of 1.2–3.0 pg/kg bw/d, a considerable proportion of the European population would still exceed the TWI derived by the Committee.'*

The EC-SCF noted that the most sensitive endpoints in animal studies were developmental and reproductive effects in rats and monkeys and endometriosis in monkeys and that the TWI they established would adequately protect against the carcinogenic effects of TCDD which require substantially higher body burdens and for which a threshold approach is applicable due to its non-genotoxic nature.

In the rat carcinogenicity study (Kociba et al, 1978) the LOAEL for liver tumours was taken as 10 ng/kg bw/day, corresponding to a body burden of 294 ng TCDD/kg bw. In order for humans to obtain a similar steady-state body burden, a daily intake of 150 pg/kg bw would be needed. The EC-SCF also concluded that rats were more sensitive than humans to the carcinogenic effects of TCDD (based on a body-burden comparison), albeit within less than one order of magnitude.

The Committee emphasised that it did not perform a quantitative risk assessment of the health risk associated with exposure to dioxins and dioxin-like PCBs because "the available data on high dose animal studies and studies of human occupational and accidental exposures cannot be extrapolated quantitatively with any confidence down to values corresponding to the background exposures of the general population". It further noted that the TWI is not a lower bound of toxicity, it is an estimate of a safe level of intake and is derived conservatively using uncertainty factors applied to NOAELs or LOAELs. Thus, slight exceedance of the TWI does not mean that there is an appreciable risk to health of individuals, but that exposure above this level leads to an erosion of the protection embedded in the TWI.

### 2.3.6 Assessment by the FAO/WHO 57th JECFA meeting (2001)

The Joint FAO/WHO Expert Committee on Food Additives (JECFA) evaluated dioxins at its 57th meeting in Rome, in June 2001 (FAO/WHO, 2001)[20]. JEFCA serves as the scientific advisory body to the Codex Alimentarius Commission (CAC) on matters relating to food additives, contaminants, and residues of veterinary drugs in food. The CAC sets international food standards aimed at protecting the health of consumers and facilitating international trade in foods.

#### *2.3.6.1 Conclusions from the JECFA*

The JECFA meeting concluded that a tolerable intake for TCDD could be established, based on reproductive effects in the male offspring of TCDD-treated rat dams. For assessment of tolerable intake, JECFA chose the LOEL established in the study of Faqi et al (1998) and the NOEL provided by the study of Ohsako et al (2001). Two different models were used to estimate the equivalent maternal body burden with long-term dosing: a model that assumed a linear relationship between maternal and foetal body burden, and a nonlinear model (see Table 2-6). After compensating for the background body burden of PCDDs and PCDFs found in untreated rats, JECFA derived estimated human monthly intakes (EHMIs) of 237 and 330 pg TEF/kg bw, using the linear and nonlinear models, respectively, from the study by Ohsako et al (2001). The corresponding EHMI values derived from the study by Faqi et al (1998) were 423 and 630 pg TEF/kg bw.

The committee then derived safety factors to apply to the EHMI values. In common with the 1998 WHO consultation, JECFA considered that the use of body burdens to scale doses from animals to humans removed the need to account for interspecies differences. To account for differences between individuals in human toxicokinetics, a safety factor of 3.2 was applied to the EHMIs associated with the NOEL identified by Ohsako et al (2001). No additional safety factor was applied to account for differences in human toxicodynamics. A larger safety factor was applied to the EHMI associated with the LOEL identified by Faqi and co-workers. JECFA considered that use of a LOEL warranted an additional safety factor of 3, leading to an overall safety factor of (3 x 3.2) = 9.6. The four resulting provisional tolerable monthly intake (PTMI) values ranged from 44 to 103 pg/kg bw/month.

**Table 2-2 JECFA derivation of provisional tolerable monthly intake values from reproductive toxicity in rats**

| Study | Linear model | | Nonlinear model | |
|---|---|---|---|---|
| | Ohsako et al (2001) | Faqi et al (1998) | Ohsako et al (2001) | Faqi et al (1998) |
| End point (in male offspring of treated dams) | NOEL (decreased anogenital distance at higher doses) | LOEL (decreased sperm production, sexual feminisation) | NOEL (decreased anogenital distance at higher doses) | LOEL (decreased sperm production, sexual feminisation) |

[20] The Australian delegate to the 57th meeting of the JECFA was Dr Peter Abbott, Food Standards Australia New Zealand (FSANZ), Canberra, ACT

| Study | Linear model | | Nonlinear model | |
|---|---|---|---|---|
| | Ohsako et al (2001) | Faqi et al (1998) | Ohsako et al (2001) | Faqi et al (1998) |
| Maternal TCDD body burden (ng/kg bw) | 7.6 | 25 | 7.6 | 25 |
| Equivalent maternal body burden with long-term dosing (ng/kg bw) | 13 | 25 | 19 | 39 |
| Background body burden (ng/kg bw) | 3 | 3 | 3 | 3 |
| Total body burden (ng/kg bw) | 16 | 28 | 22 | 42 |
| Equivalent EHMI (pg/kg bw/mo) | 237 | 423 | 330 | 630 |
| Safety factor | 3.2 | 9.6 | 3.2 | 9.6 |
| Derived PTMI value (pg/kg bw/mo) | 74 | 44 | 103 | 66 |

Taking the mid-point of the range, JECFA chose a PTMI for PCDDs, PCDFs and coplanar compounds of 70 pg TEF/kg bw/month. JECFA was satisfied that establishment of a tolerable intake based on non-cancer effects would also address any carcinogenic risk. The committee noted that in a long-term study in rats in which the incidence of liver tumours was increased over that in controls, the LOEL of 10 ng/kg bw/day corresponded to a steady-state body burden of 290 ng/kg bw/day; in order for humans to attain a similar steady-state body burden, they would have to have a daily intake of 150 pg/kg bw. Although the excess cancer risk at the highest exposures in human epidemiology studies was statistically significant, the JECFA commented that these results needed to be evaluated with caution as the overall risks were not high and the strongest evidence was for industrial populations with exposures two to three orders of magnitude greater than that of the general population, and also with heavy exposure to other chemicals. Furthermore, lifestyle factors such as smoking were not evaluated. It was noted, *inter alia*, that there were few precedents of carcinogens that increase the risk for cancer at all sites combined, with no excess risk for any specific tumour predominating. A "benchmark dose" was calculated from the effective dose estimated to result in a 1% increase in cancer mortality (ED01), on the basis of a meta-analysis of data for three industrial cohorts with well-documented exposure. However, the ED01 differed quite widely and depended strongly on the assumptions made. Furthermore, a number of uncertainties would influence the predicted ED01, including the exact exposure of the occupational cohorts and, to a lesser extent, the effects of factors not considered.

The Committee concluded that a tolerable intake could be established for TCDD on the basis of the assumption that there is a threshold for all effects, including cancer. Carcinogenicity due to TCDD was not linked to mutagenicity or DNA binding, and it occurred at higher body burdens in animals than other toxic effects. Thus the Committee concluded that the establishment of a tolerable intake based on effects other than cancer would also address any carcinogenic risk.

The JECFA report stated that:

'*the PTMI is not a limit of toxicity and does not represent a boundary between safe intake and intake associated with a significant increase in body burden or risk. Long-term intakes slightly above the PTMI would not necessarily result in adverse health effects but would erode the safety factor built into calculations of the PTMI. It is not possible given our current knowledge to define the magnitude and duration of excess intake that would be associated with adverse health effects.'*

The report also indicated that '*despite the uncertainties, the results suggest that a considerable fraction of the population will have a long-term mean intake above the PTMI'*.
In view of the long half-lives of PCDDs, PCDFs and PCBs, the committee concluded that it would not be appropriate to establish an acute reference dose for these compounds.

### 2.3.7 Other Published Assessments

#### *2.3.7.1 Exponent, USA*

A published study by Exponent, a major independent US consulting firm (Greene et al, 2003; Greene & Paustenbach, 2002) reviewed published studies involving laboratory animals and humans which addressed non-cancer effects. The analysis confirmed that developmental toxicity was the most sensitive effect of TCDD consistently seen in mice and rats; a NOAEL of 13 ng/kg (maternal body burden) was identified as the most pertinent for deriving a reference dose (RfD) for humans. Using this NOAEL and assuming 50% bioavailability, the equivalent human body burden is achieved with a daily dose of approximately 7 pg/kg bw/day. The authors noted that the use of body burden rather than dose, and the fact that male rat foetuses were the most susceptible population, it was appropriate to use safety factors of 1 for both inter-individual variation and sensitive subpopulations.

In humans, the most consistent adverse effect is chloracne. From Seveso chloracne data (see above under 'Chloracne'), the peak body burden of an affected child with the lowest serum TCDD concentration was 828 ng/kg lipid adjusted, or 207 ng/kg body burden - assuming 25% lipid). Using a safety factor of 10 (for conversion from a LOAEL to a NOAEL), Greene and Paustenbach calculated an absorbed RfD of 5 pg/kg/day; assuming 50% bioavailability, this equates to 10 pg/kg bw/day as a dose safe for the development of chloracne, even in children. The true value of the dose which could cause chloracne is likely to be significantly higher because the chloracne may well have been caused by the localised concentrations of TCDD on the skin rather than the systemic body burden. Alternatively, the lower 95th percentile confidence level for the mean peak TCDD serum concentration for people with chloracne (9,729 ng/kg lipid or 2,432 ng/kg body weight – assuming 25% lipid) could be used to develop an RfD. With a safety factor of 10 to account for inter-individual variation and a further 10 to account for sensitive subpopulations, Greene and Paustenbach estimated that an RfD of 6 pg absorbed/kg/day would not cause chloracne. Assuming 50% bioavailability, this also equates to an RfD of approximately 10 pg/kg bw/day.

The authors concluded that an RfD of 5–10 pg/kg bw/day, based on chloracne in children and developmental effects in foetal rats, should be a conservative health intake value and would indicate that current consumption levels are unlikely to pose an adverse health risk in the general population. However, due to the uncertainty in our knowledge and the less-than-perfect nature of epidemiology studies, it is important to strongly support the continued reduction in emissions of TCDD and other dioxin-like compounds to the environment.

## 2.4 National Exposure Standards for Dioxins

A number of national regulatory agencies have established human exposure standards for dioxins, generally referred to as tolerable daily or weekly intakes.

### 2.4.1 Japan

Following the same principles as the WHO 1998 re-evaluation of TDI (WHO, 1998), a joint committee from the Japanese Environment Agency and the Ministry of Health and Welfare considered the establishment of a TDI for PCDD/Fs and dioxin-like PCBs (Environment Agency and Ministry of Health and Welfare, 1999; Ohno, 2001). From the data of Gehrs et al (1997) and Gray et al (1997b), they concluded that a level of approximately 86 ng/kg is the lowest maternal body burden value just below or above which effects are manifested, including female genital anomalies that were considered to be significant as a toxic endpoint. The committee noted that in some toxicity studies, effects had been observed at lower body burdens, but when dose-dependency, reliability, reproducibility and the toxicological significance of the tests were considered, they were thought to be inadequate to use as indices for human health effects; these included the studies on endometriosis (Rier et al, 1993), reduced learning ability in offspring of monkeys (Schantz & Bowman, 1989), and decreased sperm counts in offspring of rats (Gray et al, 1997a). (This latter study drove the lower limit of 1 pg TEQ/kg bw/day of the WHO TDI range of 1–4 pg TEQ/kg bw/day.) For a maternal body burden of 86 ng/kg, an estimated human daily intake of 43.6 pg TEQ/kg bw/day was derived, and, by using an uncertainty factor of 10 (as per WHO, 1998), a provisional TDI of 4 pg TEQ/kg bw/day was derived.

### 2.4.2 New Zealand

In the February 2001 report to the New Zealand Ministry for the Environment, *Evaluation of the toxicity of dioxins and dioxin-like PCBs: A health risk appraisal for the New Zealand population* (Smith & Lopipero, 2001), New Zealand intakes of dioxins and dioxin-like compounds were compared with the TDI target value established by the WHO (WHO, 1998) and the Minimal Risk Level (MRL) set by the ATSDR (ATSDR, 1998) of 1 pg TEQ/kg bw/day. However, one of the recommendations of this report was that "identifying a tolerable daily intake [for New Zealanders] is not recommended".

### 2.4.3 The Netherlands

The exposure limit derived by the Health Council of the Netherlands (1996) is the same as the lower end of the TDI range derived by the WHO (1998) of 1–4 pg WHO-TEQ/kg bw/day. The Council's Committee on the Risk Evaluation of Substances considered that studies on Rhesus monkeys that reported objective recognition effects (Bowman et al,

1989a), endometriosis (Rier et al, 1993), and prenatal death (Bowman et al, 1989b), and a study in Marmoset monkeys that reported a change in lymphocytes (Neubert et al, 1992) were the most relevant for the derivation of a health-based criterion. From these, a LOAEL of 0.1 ng/kg bw/day was determined, and considered to be equivalent to a NOAEL of 0.05 ng/kg bw/day. Safety factors of 5 (for interspecies variation between monkeys and humans) and 10 (for differences in sensitivities between humans) were applied to give an exposure limit of 1 pg/kg bw/day; the Committee considered that this limit should be applicable to the intake of mixtures of PCDD/Fs and dioxin-like PCBs, expressed as total TEQ. The Netherlands supports the objective of the European Commission's Strategy for Dioxins to reduce human intake levels to below 14 pg WHO-TEQ/kg bw per week (ie. the TWI recommended by the EC-SCF); this strategy was agreed by the European Council of Ministers in December 2001 (COM, 2001).

### 2.4.4 United Kingdom

The TDI of 10 pg TCDD/kg bw/day recommended by the WHO Expert Group in 1990 (WHO, 1991) was endorsed by the UK Department of Health's Committee on the Toxicity of Chemicals in Food, Consumer Products, and the Environment (COT) (MAFF, 1992) on the basis of carcinogenicity, and reproductive and development effects. Subsequently, the COT recommended that the TDI could be regarded as 10 pg TEQ/kg bw/day based on the combined intakes of PCDD/Fs and dioxin-like PCBs (COT, 1997). In 2001 the COT produced a detailed review on dioxins and dioxin-like PCBs (COT, 2001). The Committee concluded that the available human data did not provide a sufficiently rigorous basis for establishment of a tolerable intake, so it was necessary to base its evaluation on data from studies conducted in experimental animals. It concluded that the most sensitive end-point was the effects on the developing reproductive systems of male rat foetuses exposed *in utero*. Based on this, the COT recommended that the TDI for dioxins and dioxin-like PCBs be reduced from 10 to 2 pg WHO-TEQ per kg bodyweight. This is in line with the recommendations of other bodies such as the European Commission's Scientific Committee on Food and the Joint FAO/WHO Expert Committee on Food Additives.

## 2.5 Hazard Summary and Discussion

This hazard assessment has reviewed some of the large amount of data on the toxicology and epidemiology of dioxin-like compounds, and summarises recent hazard assessments made by international organisations and several national agencies. Reviews of experimental data by a range of national and international agencies indicate that endocrine and reproductive effects should be among the most sensitive effects in both animals and humans.

Adverse effects reported in animals following exposure to dioxins include immunotoxicity, endometriosis in Rhesus monkeys, developmental behavioural effects in offspring of treated Rhesus monkeys, and developmental effects in rats (including reproductive toxicity in males and urogenital malformations in females). The animals most sensitive to dioxin-induced adverse effects were the male offspring of treated rats. In a study by Faqi et al (1998), dams received a loading dose of 25, 60 or 300 ng 14C-TCDD/kg bw two weeks prior to mating, followed by weekly doses of 5, 12 or 60 ng/kg bw throughout mating, pregnancy and lactation. Decreased sperm production and feminised sexual behaviour were observed in male offspring at the lowest dose, which was taken as the LOEL. The Joint Expert Committee on Food Additives (JECFA) applied linear and nonlinear curve fitting techniques to derive maternal steady-state body burden estimates of 25 and 39 ng/kg bw, respectively, at this LOEL. The lowest NOEL was found in a reproduction study by Ohsako et al (2001) in which Holtzman rats received a single oral dose of 0, 12.5, 50, 200 or 800 ng TCDD/kg bw on the 15th day of pregnancy. Male offspring displayed reduced anogenital distance and androgen receptor mRNA levels in the ventral prostate, with a LOEL of 50 ng/kg bw and a NOEL of 12.5 ng/kg bw. By reference to toxicokinetic data, JECFA estimated a maternal body burden of 13–19 ng/kg bw at the NOEL and 51–76 ng/kg bw at the LOEL.

In humans, the most widely recognised and consistently observed effect following high dose exposure to TCDD is chloracne. The condition can disappear after termination of exposure or can persist for many years. Other effects on the skin include hyperpigmentation and hirsutism. Increased levels of hepatic enzymes and slight alterations in lipid profile have been reported in humans exposed to high levels of TCDD, although the effects were mild and often transient. Temporary enlargement of the liver has also been observed.

TCDD can cause long-term alteration in glucose metabolism and slight changes in thyroid function. Evidence is suggestive of a weak correlation between diabetes incidence and occupational or accidental exposure to dioxins; however, background exposure to dioxins is not a significant risk factor for individuals who have not been occupationally or accidentally exposed.

Effects on the respiratory system, manifested mainly as upper respiratory tract irritation, have resulted from acute high exposure to TCDD. Other irritant effects resulting from acute exposure include conjunctivitis with red and irritated eyes, and blepharitis.

Clinical illness associated with immune system disorders does not appear to have been associated with TCDD in any cohort studied.

There is some suggestive evidence of toxicity to the cardiovascular system. Some studies report that higher exposure to dioxins is associated with hyperlipidemia and increased frequency of ischaemic heart disease, valvular heart disease, and retinopathy.

While dioxins can increase the incidence and severity of endometriosis in monkeys, epidemiology studies and small, hospital-based case-control studies have failed to provide compelling evidence for or against an association of environmental contaminants and endometriosis in humans.

Results from human studies of developmental effects and exposure to TCDD have generally been inconclusive. Studies of the risk of spontaneous abortion involving occupational and environmental herbicide exposure have generally not found increased risks. Several studies indicate that paternal exposure to dioxins may be associated with the birth of more girls than boys; however, the median concentration of dioxin in fathers in a study on a Seveso cohort was about 20 times the estimated average concentration of TCDD currently found in human beings in industrialised countries.

The potential neurotoxicity of PCBs was first recognised when people in Japan (1968) and Taiwan (1978-1979) consumed rice oil contaminated with PCBs and PCDFs; offspring had poorer cognitive functioning as well as other behavioural problems. In the recent Dutch PCB/dioxin study, assessment of school-age children suggested that subtle cognitive and motor developmental delays arising from prenatal PCB and dioxin exposure were seen when parental and home characteristics were less optimal but such effects were not measurable in children raised in more optimal environments. Nevertheless, findings on studies on children exposed to near background levels of PCBs and dioxins are controversial; the application of causation analysis to 24 epidemiology studies that sought an association between maternal PCB exposure and neurodevelopmental effects led to the conclusion that although there is biological plausibility, a causal association was without empirical support. A US study indicated that performance of more highly PCB-exposed breast-fed children was not diminished but was positively correlated with duration of breast-feeding.

Recently data has been collected from animal and human studies which raise concerns that teeth development may be a sensitive target for dioxin toxicity. Dental hard tissues (ie. enamel and the dentin) are not remodelled once they have been formed and hence disturbances in the function of the enamel-forming ameloblasts and the dentin-forming odontoblasts are permanent in nature and thus amenable to investigation. Whilst there is evidence of effects on tooth development arising from significant exposures to dioxin-like compounds in animal studies and humans (Yusho, Yu-Cheng and Seveso incidents), recent results from Finnish studies are not so clear cut with respect to population exposures to general ‘background’ levels. Certainly, prevailing levels of PCDD/Fs and PCBs in Finland appear to be below the threshold to cause perinatal eruption of teeth. A firm conclusion on whether hypodontia and mineralisation defects are associated with pre- and/or perinatal exposure to dioxin-like compounds would appear to require further studies involving larger numbers of children.

Of the range of non-cancer health effects evaluated in exposed adult populations, some appear to be transient and not observed when exposure ceased, whereas other effects persist for some years. Overall, epidemiology studies on populations exposed occupationally or environmentally to TCDD have not demonstrated any significantly increased all-cause or non-cancer mortality.

Epidemiological evidence from the most highly TCDD-exposed cohorts studied produces the strongest evidence of an increased cancer risk from exposure to dioxins, when the data are considered for all cancers combined. There is weaker evidence of an increased cancer risk when the data for cancers at particular sites are considered. In specific cohorts, excess risks were observed for reproductive cancers (female breast, endometrium, male breast, testis) but, overall, the pattern is inconsistent. The relative risk estimates are generally low, they are relatively consistent across studies with the highest exposures. While they are not likely to be explained by confounding, this possibility cannot be excluded.

It is difficult to find epidemiological data that have sufficient dose-response information to provide reliable risk estimates for cancer in exposed human populations. Modelling is complicated by uncertainties in extrapolating current body burdens of dioxins to past occupational exposure and by the choice of the dose-response model to fit the data. Scientific debate about the potential human carcinogenicity of dioxin-like compounds has been ongoing for many years and recent meta-analyses from three occupationally-exposed cohorts have reached such different conclusions that the debate on the carcinogenic potency of dioxins will continue for quite some time.

Three recent key international evaluations have established that hormonal, reproductive and/or developmental effects are the most sensitive indicators of dioxin-related toxicity in experimental animals. Despite some differences in the most significant studies and in the methodology used to analyse the data, the WHO, the EC-SCF and JECFA reached similar conclusions and recommended a similar health intake standard. As shown in Table 2-3, when expressed in terms of daily dose, the human intake standards proposed by the EC-SCF and JECFA lie close to the mid-point of the TDI range of 1–4 pg TEQ/kg bw/day proposed by the WHO consultation.

**Table 2-3 Comparison between the standards (as TEQ) for human intake of dioxins, furans and dioxin-like PCBs agreed by WHO (1998), EC-SCF (2001) and JECFA (2001)**

| Exposure standard | pg kg bw/day | pg/kg bw/week | pg/kg bw/mnth |
|---|---|---|---|
| WHO consultation (1998) | **1–4** | 7–28 | 30–120 |
| EC-SCF (2001) | 2 | **14** | 60 |
| JECFA (2001) | 2.3 | 16.3 | **70** |

Note: The recommended exposure standards are shown in bold, with conversions to a daily, weekly or monthly basis in plain type.

In 2002 Australia recommended a Tolerable Monthly Intake (TMI) for Australians of 70 pg TEQ/kg bodyweight from all sources combined, and including polychlorinated dioxins, polychlorinated furans and dioxin-like PCBs (NHMRC/TGA, 2002), this value being equivalent to that set by the JECFA. It was suggested at that time that this TMI be

reviewed following any further hazard evaluation of dioxins by international agencies, or the publication of significant new findings.

This re-assessment notes that, although the cancer hazard posed by this chemical has probably received the bulk of attention over the past 20 years, non-cancer hazards are likely to be more important than the cancer hazard at current background levels to which the general public may be exposed. In studies in animals, developmental toxicity appears to be most sensitive effect of TCDD, consistently seen in mice and rats. A range of adverse effects following dioxin exposure have been reported in various epidemiology studies in humans over the past 25 years, of which the most consistently reported adverse effect is chloracne.

Based on our analysis of various international hazard assessments and relevant literature published between 1999 and late 2003, it is considered that the Australian TMI of 70 pg/kg bw/month as recommended by the NHMRC and the TGA's Office of Chemical Safety should be adequately protective of the general population with respect to effects of dioxin-like compounds. Nevertheless, in view of uncertainties in the data and of adverse trends or findings in populations with higher exposures than the general public, continuing efforts should be made to minimise releases of these compounds to the environment.

Whilst several agencies have recommended against the establishment a health reference dose (eg. the US EPA, the NZ Ministry for the Environment), it is noted that the majority of the panel members of the US EPA's Science Advisory Board (SAB) recommended to the EPA that an RfD should be set.

# 3. Exposure Assessment

## Methodology and Terminology

In conducting a human exposure or intake assessment, use is made of analytical data on levels of dioxin-like compounds in foodstuffs and various environmental media. With respect to exposure to dioxin-like compounds, this exposure assessment focuses on 17 PCDDs and PCDFs and 12 co-planar PCBs which are included in the WHO TEQ. Issues to be considered include how representative of the foodstuff or environmental medium was the sampling and how accurate was the assay method. Furthermore, interpretation of reported data are complicated by different ways in which congeners that are not actually detected are represented in sums or averages. Such non-detects need to be considered since a non-detect can mean that the compound is not there, or that the assay method used was not sufficiently sensitive to detect it. In other cases, the methodology may detect a compound but not be sufficiently sensitive to accurately quantify it.

When dioxin-like PCDD/PCDF and/or PCB congeners are not detected in an assay, there are three ways of incorporating such non-detects into the estimate of total TEQ levels. The non-detected congeners can be taken to be present at zero concentration, in

which case the TEQ estimated is the *lower bound* estimate. If non-detects are taken as being present at the Limit of Detection (LOD)[21] of the assay, then the TEQ reported is the *upper bound* estimate. The lower-bound and upper-bound estimates correspond to the minimum concentration known to be present and to a larger concentration that might be present. In almost every case, the upper bound will be an overestimate of the true value, the degree of over-estimation decreasing with increasing assay sensitivity. If non-detects are assumed to be present at 1/2 the LOD, the TEQ parameter is referred to as the *medium bound* estimate. It should be noted that if the lower bound and upper bound totals are far apart (as is often the case, particularly when assay methodology is not particularly sensitive), the medium bound estimate is not necessarily any closer to the 'true' TEQ than is either of the other two estimates. In the light of the issues above, comparisons of data collected by different programs and measured by different laboratories has to be carried out with great caution (Startin & Rose, 2003).

In the following Chapter, TEQ values estimated in different studies are sometimes compared. It should be noted several ways of calculating TEQ values have been developed eg. the Nordic TEQ (N-TEQ), the International TEQ (I-TEQ) and the WHO-TEQ. The N-TEQ (no longer used) differs from the I-TEQ mainly in that in the N-TEQ the octa-dioxin/furan congeners are not counted, while in I-TEQ they are given a TEF of 0.001; this would result in N-TEQ calculations being slightly lower than the equivalent I-TEQ calculations. WHO-TEQ values are based on the most recent scientific consensus (Van den Berg et al, 1998), withdrawing TEFs for the di-ortho PCBs (PCB170 and 180) that were assigned earlier and revising TEFs for 1,2,3,7,8-pentaCDD, octaCDD, octaCDF and PCB77. Recalculating I-TEQs as WHO-TEQs would commonly result in an approximately 10% increase in TEQ levels (Van Leeuwen et al, 2000; Smith & Lopipero, 2001). The differences between the respective TEFs are not great. Although the most important dioxin-like PCBs have been given TEF values, it should be appreciated that PCBs may interact with cellular sites other than the *Ah* receptor and therefore have some other effects that cannot be expressed in terms of TCDD equivalence. For more information on the TEQ concept and its use, see Ahlborg et al (1994) and Van den Berg et al (1998) and Appendix XVIII for a comparison of TEFs.

## 3.1 Current Levels in the Australian Population

### 3.1.1 Blood serum analysis

The aim of the study by Harden et al (2004) was to measure the serum levels of polychlorinated dibenzo-p-dioxins (PCDDs), polychlorinated dibenzofurans (PCDFs) and polychlorinated biphenyls (PCBs) in pooled blood serum collected throughout Australia between 2002-2003. De-identified serum samples were selected from surplus pathology samples and stratified according to gender, age and region, as follows:

[21] LOD – the lowest concentration of a chemical that can be qualitatively detected using a specified laboratory method (ie. it can be detected but not quantified). This may be compared with the Limit of Quantitation (LOQ), the lowest concentration of a chemical that can be detected and quantified with an acceptable degree of certainty.

*Age Stratification*

- <16 years (0 – 15 years, born 1987-2002 inclusive)
- 16-30 years (16-30 years, born 1972-1986 inclusive)
- 31-45 years (31-45 years, born 1957-1971 inclusive)
- 46-60 years (46-60 years, born 1942-1956 inclusive)
- 60 years (> 60 years of age, born in 1941 or earlier)

*Geographic Stratification*

- Four urban regions:
  - Northeast (Brisbane, Tweed and Gold Coast and other major population centres in Queensland);
  - Southeast (Sydney, Canberra, Wollongong, Newcastle and other major population centres in New South Wales);
  - South (Melbourne, Adelaide, Hobart and other major population centres in Victoria);
  - West (Perth and other major population centres in Western Australia)
- One rural region:
  - Including rural areas from all States and the Northern Territory, according to the population distribution

Where there were sufficient numbers of samples collected for each of the 50 strata, each stratum was represented by duplicate pools, analysed independently. For individuals less than 16 years old from the South and West urban regions, there were insufficient numbers of samples available, hence samples in these strata were assayed as a single pool for each gender and region, rather than in duplicate. In total, 9090 samples from the 50 strata were collected and pooled to give 96 pools.

With the exception of the number of samples collected for either sex aged <16 years in the West and South urban regions, the number of samples in each stratum was between 122-202, with an average of 193 ± 18 samples. The number of samples collected for the strata <16 years in the South and West regions were between 67-68 and 24-28, respectively. The approximate percentage of the population represented by each age strata was between 5-10%. The approximate percentage of the total Australian population represented by the 5 regions; Northeast, Southeast, South, West urban regions and one rural area were 25, 20, 9, 7 and 19% respectively. Figure 3-1 shows the geographical distribution of the collection regions.

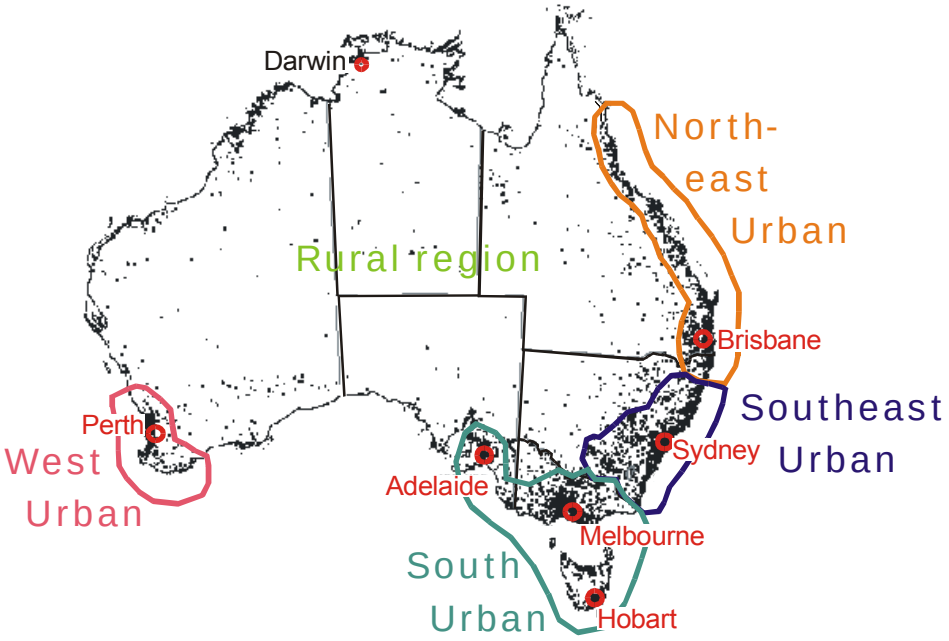

**Figure 3-1 Map indicating the sampling regions of four major population areas of Australia.**

The population density of each region is indicated in black (2002 data from the Australian Bureau of Statistics).

All pooled samples were sent to ERGO-Forschungsgesellschaft mbH, Hamburg, Germany for analysis, and 10 duplicate samples were sent to Health Canada, Ottawa, Canada for inter-laboratory comparison. Both laboratories are accredited for analytical dioxin analysis. Inter-laboratory and intra-laboratory variation between average values was approximately 10% and within acceptable ranges. The ERGO data were analytically reproducible, exhibiting normalised differences of between 10.3 to 21.7% for the 4 pools selected, when measured in duplicate.

The decision to use surplus pathology samples (and the possible attendant bias towards individuals who may have had some degree of physiological perturbation) *vs* a specific but totally random collection of samples across the population was made on the basis of (1) procedural complexity, including the need for more staff and material resources; (2) necessity to seek consent from each participant; and (3) much lower sample numbers for a given budget. A pilot study to compare results from pathology samples (males 30-45 years old) with samples taken for the purposes of medical examination for insurance cover (males 30-45 years old) was performed. For most of the congeners, the difference was less than 20% and thus may be explained by normal variations in analytical sensitivity. The findings indicated that there was the possibility of greater variation within the same group (ie. insurance pool 1 *vs* insurance pool 2) than between the different groups (insurance and pathology).

### *3.1.1.1 Levels of PCDD, PCDFs and PCBs in Blood Serum*

Dioxin compounds accumulate in the fat stores of the human body. It is assumed that under steady-state conditions, the dioxin concentration in fat stores is equivalent to that present in the lipid fraction of the blood. Thus the dioxin concentration in blood is calculated on a lipid weight basis.

The concentrations of PCDD/Fs and PCBs, as TEQs calculated using WHO-TEFs (Van den berg et al, 1998) on lipid weight basis, are expressed as upper and lower bound TEQ. Only the upper bound TEQ values are reported in the text. Both lower and upper bound TEQ values stratified by age group, sex and region are recorded in Appendices (Appendix VII and VIII).

#### *3.1.1.1(a) Total PCDDs, PCDFs plus PCBs*

Table 3-1 gives the results for total WHO-TEQ (PCDD/Fs plus PCBs) for all analysed pools from the 5 age groups and regions for each sex.

**Table 3-1 Australian serum levels of total dioxins (WHO-TEQ ng/kg lipid) measured in two pools (P1, P2) by age group, gender and region.**

| Sex | Age (years) | Northeast Urban | | Southeast Urban | | South Urban | | West Urban | | Rural Area | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | | **P 1** | **P 2** | **P 1** | **P 2** | **P 1** | **P 2** | **P 1** | **P 2** | **P 1** | **P 2** |
| Male | <16 | 5.9 | 5.6 | 8.0 | 5.8 | 6.1 | N/A | 6.5 | N/A | 6.5 | 6 |
| | 16-30 | 5.8 | 5.0 | 5.9 | 7.6 | 6.0 | 5.4 | 4.7 | 4.9 | 5.3 | 6.6 |
| | 31-45 | 7.2 | 7.3 | 8.2 | 11 | 6.5 | 8.1 | 7.7 | 9.8 | 7.1 | 8.0 |
| | 46-60 | 12 | 15 | 13 | 14 | 14 | 12 | 11 | 10 | 12 | 12 |
| | >60 | 17 | 19 | 22 | 18 | 19 | 20 | 18 | 19 | 16 | 19 |
| Female | <16 | 5.5 | 5.3 | 6.3 | 7.3 | **4.6** | N/A | 5.9 | N/A | 8.3 | 6.8 |
| | 16-30 | 5.8 | 6.1 | 7.1 | 8.1 | 6.0 | 4.9 | 4.8 | 5.3 | 6.1 | 6.5 |
| | 31-45 | 9.0 | 7.7 | 14 | 11 | 7.3 | 7.6 | 7.2 | 7.2 | 8.6 | 9.8 |
| | 46-60 | 14 | 12 | 15 | 16 | 11 | 10 | 9.7 | 9.9 | 12 | 12 |
| | >60 | 25 | 22 | 25 | **28** | 21 | 19 | 19 | 21 | 22 | 27 |

Data are given as upper bound values for PCDD/Fs plus PCBs
N/A = only one sample pool was analysed due insufficient number of samples.
Bold text = maximum and minimum values

The mean total WHO-TEQ (PCDD/Fs plus PCB) for all pooled samples was 10.90 ng WHO-TEQ/kg lipid. For males and females, the mean levels were 10.35 ng WHO-TEQ/kg lipid and 11.48 ng WHO-TEQ/kg lipid, respectively.

The serum levels of total dioxins expressed as TEQ varied by a factor of 6.1 from a minimum of 4.6 ng WHO-TEQ/kg lipid detected in South urban females <16 years (pool 1) to a maximum value of 28 ng WHO-TEQ/kg lipid in Southeast urban females >60 years (pool 2) (refer to bold type in Table 3-1).

*3.1.1.1(b) Contribution from PCDDs and PCDFs*

Total PCDDs and PCDFs across all regions were very similar (see graphs in Appendix II). The mean total PCDD/Fs by age group and sex, averaged across all regions is shown in Table 3-2. The levels of total PCDD/Fs increased with increasing age of the donor. The levels of total PCDD/Fs expressed as TEQ varied by a factor of 5.9 from a minimum value of 2.9 ng WHO-TEQ/kg lipid detected in Southeast females <16 years (pool 2) to 17 ng WHO-TEQ/kg lipid detected in Southeast females >60 (pool 2). There was a tendency for PCDD/Fs to be marginally higher in individuals from the Southeast and rural regions compared to Northeast, South and West regions (refer to appendix II). The contribution of PCDD/Fs to the total dioxin TEQ across all regions and age groups was between 59-67%.

*3.1.1.1(c) Contribution from PCBs*

As with PCDD/Fs, there is a general trend of increasing PCB concentrations with age (Table 3-2). This age trend was evident from individual congener data, the sum of PCB congeners and PCB WHO-TEQ. The levels of PCBs expressed as TEQ varied by a factor of 9.2 from a minimum value of 1.3 ng WHO-TEQ/kg lipid detected in a pool of South region females 16-30 years (pool 2) to a maximum value of 12 ng WHO-TEQ/kg lipid detected in >60 year old females living in the rural region (pool 2). The contribution of PCBs to the total dioxin WHO-TEQ was between 33-41% and was similar across all regions.

*3.1.1.1(c)(i) PCB #126 and PCB #169 Loadings*

The percent contribution of PCB #126 and PCB #169 to the total WHO-TEQ for PCBs is shown in Figure 3-2 (refer to as PCB loading). PCB #126 and PCB #169 were selected for analysis because they exhibit the highest TEF values, of 0.1 and 0.01 respectively, are the most toxic of all the PCB congeners and made the greatest contribution to the total PCB TEQ for any strata (Appendix III).

There was a decrease in the PCB #126 loading from the younger strata (<16 year old, Male 61.3%; Female 69.7%) compared to the older strata (>60 year olds, Male 38.7%; Females 43.0%), across the 5 regions, despite the increasing total PCB WHO-TEQ with age. Across all age groups, individuals located in the Southeast region had marginally higher PCB #126 loadings compared to other regions, with females and males exhibiting a 7-15% and 1-8% increase in PCB #126 loading, respectively. Generally females exhibited ~5% higher PCB #126 loading than males of similar age within the same region (Figure 3-2).

The mean percent contribution of PCB #169 to the total PCB WHO-TEQ was less than 5% across the 5 regions and age groups for both sexes. The PCB loading of #169 was significantly less than PCB #126 due to the 10-fold lower TEF value. Individuals in the West region exhibited marginally higher PCB #169 loadings compared to other regions, with males and females exhibiting <0.8% increase in PCB #169 loading. On average, males exhibited approximately 1% higher PCB #169 loading compared to females in the same age group (Figure 3-2).

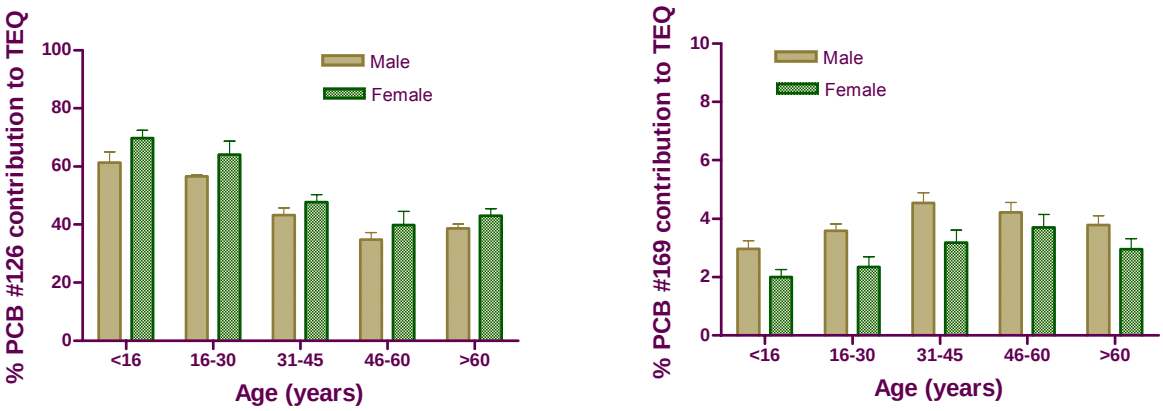

**Figure 3-2 Percent contribution of PCB #126 and PCB #169 to the total PCB WHO-TEQ for a representative sample of the Australian population.**

Data shown represents % contribution of PCB #126 and PCB #169 to the total WHO-TEQ for PCBs (upper bound).

**Table 3-2 Serum concentrations of PCDD/Fs, PCBs and total dioxins (PCDD/Fs plus PCBs) of Australians by age group and gender averaged across regions.**

| Sex | Age (years) | Serum concentration across regions (ng WHO-TEQ/kg lipid)[#] | | |

# TEQs calculated using the 1998 WHO-TEFs. Data reported as upper bound TEQs. Bold print indicates maxima, minima for PCDD/F, PCB or Total WHO-TEQ.

$ This does not correspond to a summation of the PCDD/F TEQ and PCB TEQ levels reported in the table, because the minimum PCDD/F TEQ and PCB TEQ occur in different samples, and similarly the maximum PCDD/F TEQ and PCB TEQ are for different samples.

* Minima, maxima and means were calculated using data from individual pools for males <16 and females <16 from the South Urban and West Urban regions.

### *3.1.1.2 Analysis of the factors that affect the concentration of dioxins in human blood sera*

Exposure to persistent organic pollutants and subsequent body burden can be influenced by a range of factors including the age and sex of donor and the region in which the donor resides. Note that in this study, sample donors may have only resided in the area from which the sample was collected for a short period of time. Furthermore, the study design did not allow assessment of whether individuals within a particular pool had been excessively exposed to dioxin-like compounds through either diet or occupation.

#### *3.1.1.2(a) Effect of age on serum levels of PCDD/Fs and PCBs*

Figure 3-3 indicates the effects of age on the levels of total dioxins (PCDD/Fs plus PCBs) in males and females from each of the 5 regions. For all regions, the WHO-TEQ for total dioxins increased with age from the 16-30 years of age group onwards.

There was a clear trend of increasing levels of total dioxins (PCDD/Fs plus PCBs, expressed as WHO-TEQ) from the younger strata (16-30 years; 5.88 ± 0.42 ng WHO-TEQ/kg lipid) to the older strata (>60 years; 21.39 ± 0.91 ng WHO-TEQ/kg lipid) in samples from all regions. Notably, this increase in concentration only applies from the second youngest age group onward whereas no difference was observed between the concentrations in the 0-16 year old groups (6.19 ± 0.41 ng WHO-TEQ/kg lipid) and the 16–30 year old groups (5.88 ± 0.32 ng WHO-TEQ/kg lipid).

Because of the limited number of samples, pooling of samples, and limited stratification of subjects sampled, it is not possible to detect whether females who breast fed would have lower levels of dioxins than those who did not; this investigation would require a more detailed study.

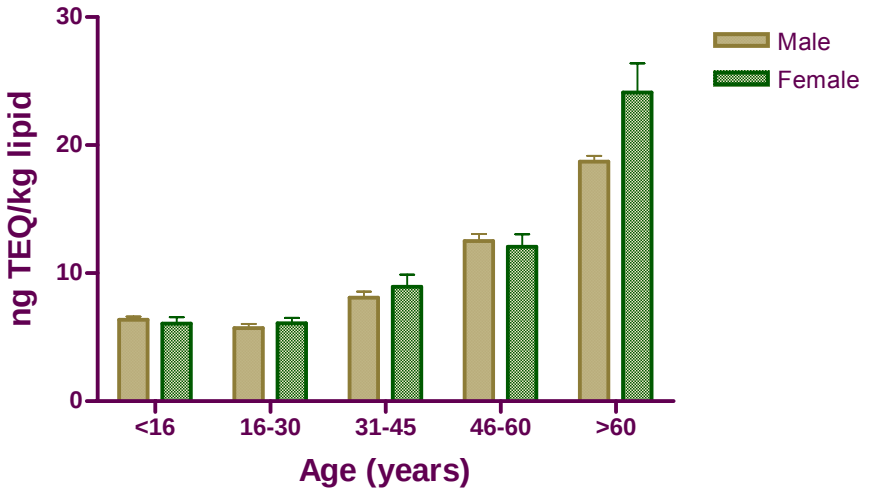

**Figure 3-3 Mean total dioxin (PCDD/Fs plus PCBs) WHO-TEQ in the serum of a representative group of Australian population, by age and sex.**

Data shown represent average upper bound WHO-TEQ values for pooled samples across 5 regions obtained for males and females from 5 age groups.

Many studies (Buckland et al, 2001; Wittsiepe et al, 2000; Schuhmacher et al, 1999; Jimenez et al, 1996) have shown that serum concentrations of dioxin compounds (PCDD/Fs and PCBs) increase with increasing age of the individual. One factor influencing this is the fact that older people were exposed to higher environmental levels of dioxins than those growing up now; this is discussed in further detail below.

*3.1.1.2(b) Regional differences in the levels of PCDD/Fs and PCBs*

Within age groups, the levels of PCDD/Fs, PCBs and total dioxins (PCDD/Fs plus PCBs) in serum appear to be very similar across all regions. With the exception of the <16 year old females, the serum concentrations from the Southeast region exhibit marginally higher levels of total dioxin WHO-TEQs compared to the West, South, Northeast urban and rural regions. For <16 year old females the highest levels of total dioxins were found in the rural region (Figure 3-4). With the exception of older rural females (>60 years), total dioxin WHO-TEQ values were similar between urban and rural areas. Rural women from the older strata (>60 years old; 25.4 ng WHO-TEQ/kg lipid) had a higher total dioxin WHO-TEQ compared urban females of the same age (22.0 ng WHO-TEQ/kg lipid averaged across the 4 urban regions).

Given that the major route of exposure for dioxins is via the diet and that the food that is consumed throughout Australia is derived from similar sources, the level of dietary exposure would be very similar across the country[22]. Thus it was not surprising that no significant regional differences in the levels of dioxins in blood serum were observed.

[22] Like the USA, nutritional exposure is subject to national food distribution systems (IOM, 2004).

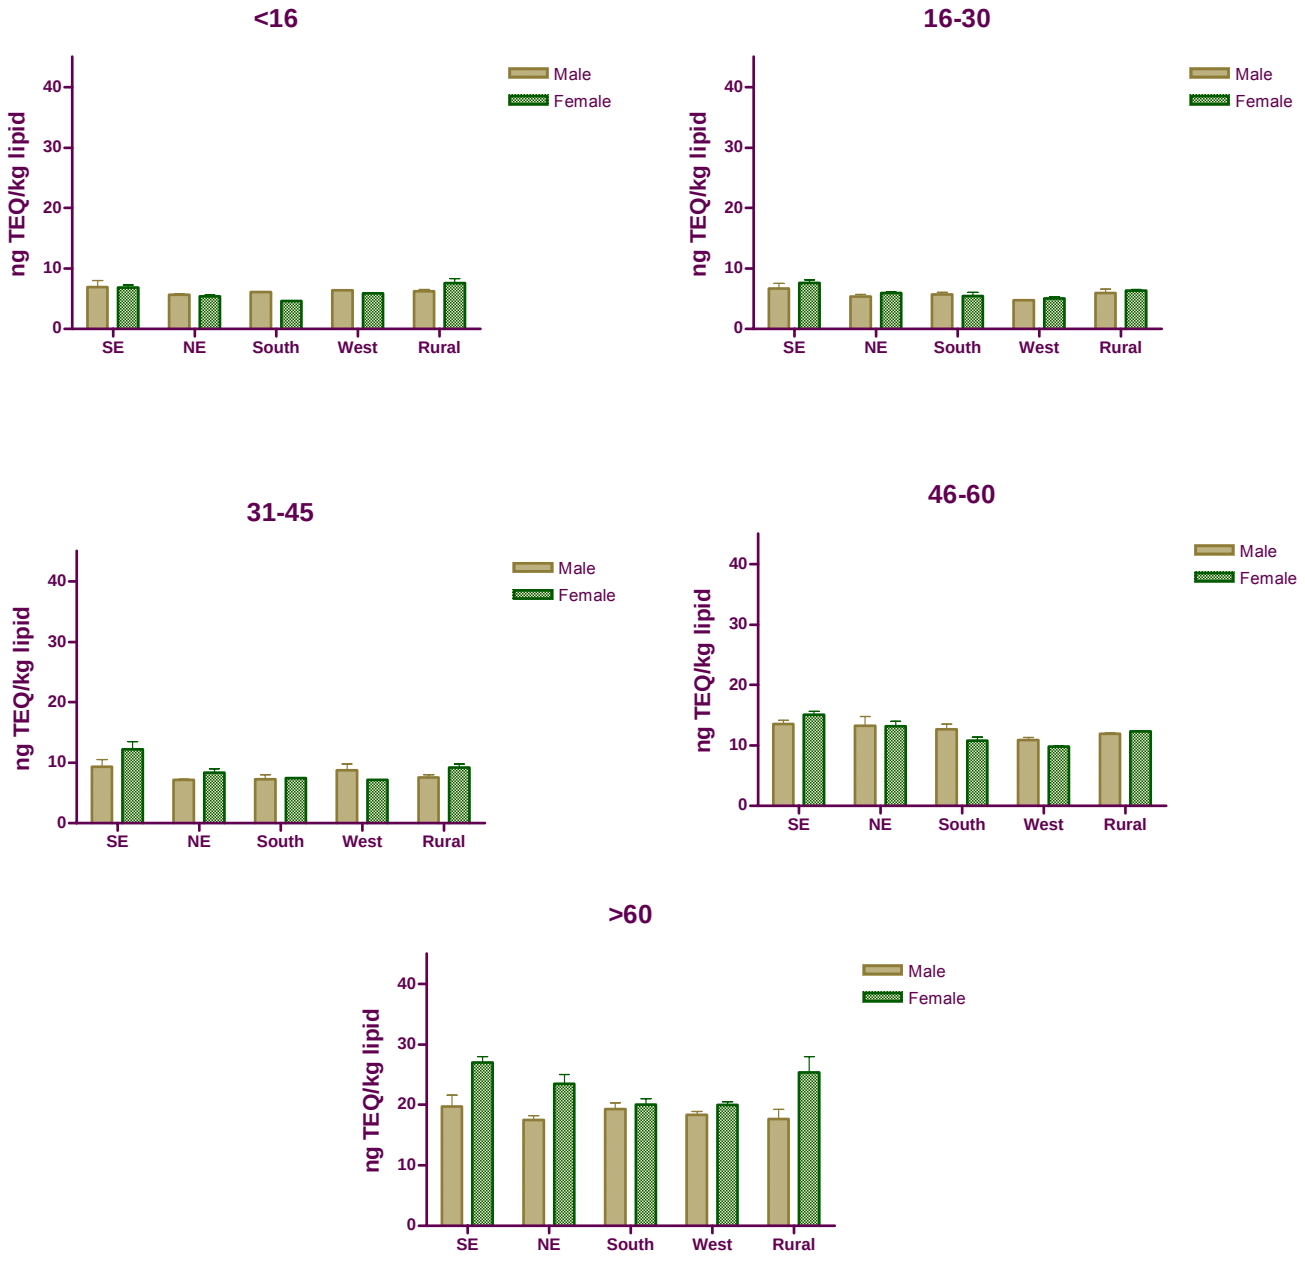

**Figure 3-4 Mean total dioxin (PCDD/Fs plus PCBs) WHO-TEQ in the serum of a representative group of the Australian population by sex, age group and region.**

Data shown represent average upper bound WHO-TEQ values for pooled samples across 5 regions obtained for males and females from the 5 age groups.

*3.1.1.2(c) Effects of gender on the levels of PCDD/Fs and PCBs*

With the exception of the >60 years age group, the total dioxin (PCDD/Fs plus PCBs) WHO-TEQ per unit lipid did not show any systematic difference between males and females. For the >60 years age group, the total dioxin WHO-TEQ for females appears to be slightly higher than males. This difference cannot be explained by differences in the average age as these were remarkably similar for males and females.

In females, the absolute amounts of total dioxin WHO-TEQs per unit body weight would be higher than in males are due to their increased percent body fat (refer to body burden section).

*3.1.1.3 Comparison of serum levels with International Data*

*3.1.1.3(a) Comparison of Australian serum levels of PCDD/Fs with other countries*

A comparison of the Australian levels of PCDD/Fs with those from other countries is depicted in Figure 3-5. Data can be found in tabular form in Appendix IV.

*3.1.1.3(a)(i) North American studies*

Tepper et al (1997) investigated PCDD/F levels in serum of males from community residents (control group), low-exposure-potential workers and high-exposure-potential workers from a pulp and paper mill in the USA. The median PCDD/F serum level in the control group viz.19.1 pg/g lipid was not appreciably different from that in the other two exposure groups. This value is approximately 3-fold higher than the mean of 6.4 pg/g serum lipid in Australian males, a value which was obtained by averaging across all 5 age groups (see Table 3-2).

Mean PCDD/F TEQs of pre-delivery blood and postpartum blood obtained from 5 females residing in upstate New York between 1995 and 1996 were 12.1 pg/g and 10.0 pg/g lipid respectively (Schecter et al, 1998). (The authors did not state which TEFs were used in this study and the age of the donors was not specified.) These results are somewhat higher than those found in the current Australian study in which the mean PCDD/F WHO-TEQ for reproductive-age females (averaged across 16-30 and 31-45 year age groups; See Table 3-2) was 4.7 pg/g of serum lipid.

*3.1.1.3(a)(ii) European Studies*

In a study of the PCDD and PCDF levels in serum from exposed and non-exposed workers from 3 sawmills in Finland, a mean I-TEQ level of 50.4 pg/g lipid was found in the non-exposed groups from all 3 sawmills (Kontsas et al, 1998). In comparison, the mean TEQ for Australian males aged 31- 60 years (averaged across 31-45 and 46-60 year age groups given in Table 3-2) is 6.6 pg WHO-TEQ/g of serum lipid.

A study in Mataro, Spain, by Gonzalez et al (2000) assessed the levels of PCDDs and PCDFs in 201 “non-occupationally” exposed subjects, of both genders, aged between 18-69 years. The serum concentration of PCDD/Fs increased with age in both sexes and, as in the current Australian study, was slightly higher in females than males.

Another Spanish study by Jimenez et al (1996) evaluated the background serum levels of PCDDs and PCDFs in 11 non-occupationally exposed people (aged between 19-55 years) living in Madrid in 1993. Calculated I-TEQ values were 8.78 pg/g and 6.96 pg/g lipid for PCDDs and PCDFs, respectively. Total PCDD/F I-TEQ was positively correlated with age (correlation coefficient = 0.79, $p<0.01$).

In a third Spanish study in Tarragona, Schuhmacher et al (1999) determined the concentrations of PCDDs and PCDFs in individual plasma samples of 20 non-occupationally exposed subjects (7 female, 13 male). Subjects were aged between 28-62 years and lived in the vicinity of a new hazardous waste incinerator or in an industrial region. The mean I-TEQ value given was 27.0 pg/g lipid (27.7 pg/g lipid for women and 25.2 pg /g lipid for men). A significant correlation ($r = 0.565$, $p < 0.01$) between the age of the subjects and the levels of PCDD/F in plasma could be observed but no significant differences were found in relation to the specific residential area (urban or industrial).

The 3 Spanish studies discussed above found TEQs for PCDD/Fs to be higher than those found in Australia. In the current Australian study, the mean WHO-TEQ for PCCD/Fs for both sexes, aged between 16-60 years (averaged across 16-30, 31-45 and 41-60 year age groups for both sexes; see Table 3-2) was 5.65 pg WHO-TEQ/g lipid.

Covaci et al (2001) analysed concentrations of PCDDs and PCDFs in 47 pooled human serum samples from 200 women aged between 50 and 65 years living in 2 areas of Flanders, Belgium in 1999. The WHO-TEQ values for PCDDs, PCDFs and PCDD/Fs from rural and suburban areas were 25.6, 23.2 and 48.7 pg/g fat respectively. No statistical differences in individual PCDD/F concentrations between the rural and suburban areas were found, nor was there any statistical difference found between WHO-TEQs for the 2 regions. PCDD/F levels in Flemish women (approx. 49 pg WHO-TEQ/g) were found to be higher than measurements in women living in other industrialized and neighbouring countries, and were considerably higher than current mean levels in Australian females of similar age who had a mean of 11.1 pg WHO-TEQ/g lipid (averaged across 46-60 and >60 years age groups; see Table 3-2).

In Norway, Johansen et al (1996) determined the concentrations of PCDDs and PCDFs in whole blood samples from 24 consumers of crabs, and 10 referents. Subjects were males aged 40-54 years of age. The Nordic-TEQs for PCDDs, PCDFs and PCDD/Fs were 9.7, 11.4 and 21.4 pg/g fat, respectively. The authors state that they found no correlation between the level of PCDD/Fs and age. In the Australian study, a Nordic-TEQ[23] would be approximately 2% lower than the WHO-TEQ, thus the mean total WHO-TEQ for males aged between 31-60 years (average across 31-45 and 45-60 year age groups given in Table 3-2) of 6.6 pg WHO-TEQ/g lipid is significantly lower than that found in the Norwegian study.

Wittsiepe et al (2000) analysed 744 individual whole blood samples collected from Germany in 1989-1998. The gender of the sample donors was not stated. The mean

[23] The Nordic-TEQ does not include OCDD/F compounds (WHO-TEF values of 0.0001) in the calculation of the TEQ, thus using the current Australian data, the Nordic-TEQ would be less than the WHO-TEQ by approximately 2%.

levels of PCDD/Fs found were 43.7 pg I-TEQ/g lipid in 1989, 20.7 pg I-TEQ/g lipid in 1997/98 and 35.6 pg/g I-TEQ/g lipid for 1989-1998 inclusive. The average ages for the periods 1989, 1997/98 and 1989-1998 were 43.6, 44.2 and 43.1 years respectively. The authors state that PCDD/F levels exhibit a positive correlation with age for most of the congeners, the sum values and the calculated toxicity equivalents. In comparison, the mean WHO-TEQ for PCDD/Fs for Australians aged between 31-45 (both sexes; sampled during 2003), was 5.5 pg WHO-TEQ/g lipid.

Menzel et al (1998) determined the dioxin blood level of exposed and 16 unexposed workers in Germany. The levels for exposed workers were greater than unexposed workers. The median PCDD/F level was 18.5 I-TEQ pg/g blood fat for unexposed workers. In another German study, Päpke et al (1996) collected blood samples in 1994 from 134 subjects. The I-TEQ for PCDD/Fs was 19.1 pg/g lipid. Even allowing for the minor differences between I-TEQ[24] and WHO-TEQ, this value is significantly higher than the mean PCCD/F WHO-TEQ of 6.72 pg/g lipid for the Australian population across all age groups. [Note that in view of declining environmental levels over recent decades, the time difference in sampling (1994 *vs* 2003) should be taken into account.]

In a third study from Germany, Wuthe et al (1996) measured blood fat concentrations of PCDDs and PCDFs in pooled samples from children (142 boys, 144 girls, <12 years) and in individual samples from adults. The overall mean PCDD/F I-TEQ was 18.4 pg/g lipid. The children were from 3 different areas in Southern Germany, an urban industrial area, an industrial area within a rural setting and a rural area. The PCDD/F I-TEQ was 8.2, 9.0 and 10.1 pg/g lipid for the 3 regions, respectively. In the current Australian study, the mean PCDD/F WHO-TEQ for children aged <16 years was 3.9 pg/g lipid.

*3.1.1.3(a)(iii) Asian Studies*

The studies from Asia suggest that levels of PCDD/Fs in human sera are higher in Japan and lower in China when compared to the Australian data.

Kumagai et al (2002) studied the concentrations of PCDDs and PCDFs in exposed and unexposed workers in Japan. The average age of controls was 42.1 years. The mean serum WHO-TEQ of PCDD/Fs in the controls was 20.3 pg/g lipid.

From a survey of the levels of dioxins in human blood (112 women and 131 men) conducted by the Environment Agency of Japan in fiscal year 1998, the mean WHO-TEQ for PCDDs and PCDFs was 11pg-TEQ/g fat with a range of 0.91-33 pg-TEQ/g fat. A total of 234 of the 253 subjects resided in "normal environmental regions" and 19 resided in the vicinity of waste incineration facilities. There were no significant differences detected between the regions.

The Australian mean PCDD/F TEQ across both sexes and all ages was 6.9 pg WHO-TEQ/g lipid, which is lower than mean PCDD/F values from both Japanese studies discussed above.

[24] I-TEQ is approximately 10% lower than the WHO-TEQ

Schecter et al (1996) reported on the concentrations of PCDD/Fs in the general population in a city in the Jiangxi province of China. Two pools of human blood were analysed, one from participants 15-19 years of age and the other one from participants 35-70 years of age. The total dioxin WHO-TEQ in pg/g lipid was 4.8 for the 15-19 year-old age group and 6.4 for the 35-70 year-old age group. These values are similar to 3.7 pg WHO-TEQ/g lipid for Australians aged 16-30 years, but lower than 8.7 pg WHO-TEQ/g lipid found for Australians aged over 31 years. The authors note that China, in comparison with more industrialised countries, has had low background levels of dioxins and furans and that this is most likely a result of lower levels of chemical use and environmental contamination.

*3.1.1.3(a)(iv) New Zealand studies*

In a study by Buckland et al (2001), 1,834 samples were analysed for levels of PCDDs and PCDFs. Samples were obtained from people of either sex aged >15 years, Maori and non-Maori. The samples were pooled according to age, ethnicity, sex and geographic location to obtain 60 pools. The mean PCDD/F concentration across the New Zealand population aged >15 years was 12.8 pg WHO-TEQ/g lipid. The levels of PCDD and PCDF congeners increased from 6.69 pg WHO-TEQ/g lipid for the 15-24 age group to 20.7 pg WHO-TEQ/g for the >65 age group. In comparison, the Australian mean WHO-TEQ PCDD/Fs for 16-30 year olds and >60 year old groups was 3.7 and 13 pg/g lipid, respectively.

In another New Zealand study, Hannah et al (1994) reported the mean levels of WHO-TEQ PCDD/Fs in blood from 28 unexposed subjects aged between 20-60 years of either sex to be 11.5 pg/g lipid. This corresponds with results from Buckland et al (2001). In comparison, the Australian mean WHO-TEQ PCDD/Fs for 16-60 year olds was 5.65 pg/g.

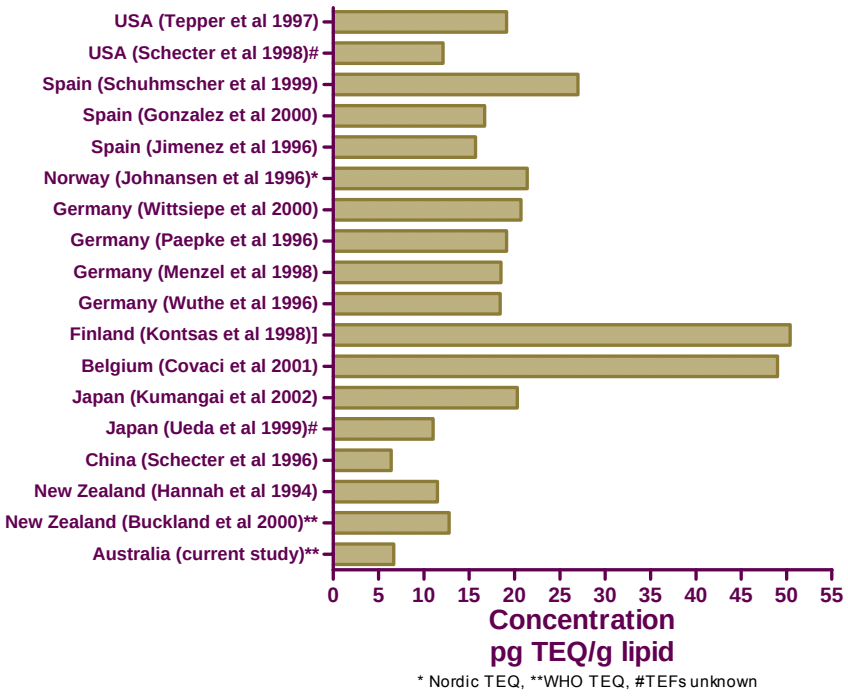

**Figure 3-5 International comparison of blood serum levels of PCDD/Fs in non-occupationally exposed populations.**

Data are reported as I-TEQs unless otherwise stated. The Nordic-TEQ does not include OCDD/F compounds (the WHO-TEF values for OCDD/F are 0.0001) in the calculation of TEQ, thus the Nordic-TEQ would underestimate the WHO-TEQ. The I-TEQ overestimates the WHO-TEQ by approximately 10%.

### *3.1.1.3b A comparison of Australian levels of PCBs with other countries*

A comparison of the Australian levels of PCB #169 and PCB #126 with those from other countries is depicted in Figure 3-6. Data can be found in tabular form in Appendix IV or in the original blood serum monitoring report (Harden et al, 2004).

It was difficult to make comparisons between the current Australian data and international data for the levels of PCBs, due to the inclusion of varying PCB congeners chosen for analysis in international studies. Furthermore, many authors have not provided TEQ values or the raw data to make these calculations.

#### *3.1.1.3(b)(i) North American studies*

Kang et al (1997) investigated PCB levels in the serum of male community residents from the USA. The study group also included low exposure-potential workers and high exposure-potential workers from a pulp and paper mill. The mean serum concentrations of PCB #126 and #169 were 18 pg/g and 27 pg/g lipid, which was similar to previous results from pooled samples of the general population and in fishermen from Quebec (Kang et al, 1997). The TEQ for PCB #126 and PCB #169 was 1.8 pg WHO-TEQ/g

lipid and 0.27 pg WHO-TEQ/g lipid, respectively. This is similar to the levels in the current study for males in the Australian population where PCB #126 was 1.58 pg WHO-TEQ/g lipid and PCB #169 was 0.15 pg WHO-TEQ/g lipid. Age, body mass index, and consumption of locally caught fish were deemed to be significant predictors for non-ortho PCB levels in human serum.

Greizerstein et al (1999) determined the levels of PCB congeners in the serum of seven lactating women in New York State, USA. The mean age of the donors was 31 years old. The sum of the congeners present above the limit of detection was used to estimate the total PCB concentration which was in the range 2.6 to 5.8 ng/g of serum. The congener contributing the greatest to the total PCBs in serum was PCB #118, with a serum concentration of 28.5 ng/g. In Australian females aged 31-45 years, the average concentration of PCB #118 was 3.6 ng/g. The authors did not report the TEQ.

In a study by Schecter et al (1998) the pre-delivery and post delivery whole blood of five women living in upstate New York was analysed in the time interval between 1995 and 1996. The mean non-*ortho* PCB concentration was 35.4 pg/g lipid for pre-delivery blood and 27.6 pg/g lipid for post delivery blood. Mean TEQ (non-*ortho* PCBs only) levels were 2.26 pg/g for pre-delivery blood and 1.70 pg/g for postpartum blood. The authors did not state which TEF were used. The concentration for PCB #126 was 21.7 pg/g lipid for pre-delivery blood and 16.3 pg/g lipid for post delivery blood. For PCB #169 the concentration was 9 pg/g lipid for pre-delivery blood and 6.7 pg/g lipid for post delivery blood. The post-delivery blood values were similar to those for Australian women aged between 16-45 years, with PCB #126 and #169 WHO-TEQ values of 7.0 and 16.1 pg/g lipid.

Shadel et al (2001) determined the levels of four PCB congeners (# 77, #81, #126 and #169) in a group of 150 men and women in Missouri, USA. Subjects had no documented exposure to PCBs. The concentration of PCB #126 was 10.8 pg/g lipid and for PCB #169 was 15.7 pg/g lipid. The TEQs for PCB #126 and PCB #169 were 1.08 pg and 0.16 pg WHO-TEQ/g lipid, respectively. The corresponding WHO-TEQ values for the Australian population were 1.8 pg WHO-TEQ/g lipid and 0.13 pg WHO-TEQ/g lipid. (PCB #126 WHO TEQ calculated from current study using the non-detect value and the maximum value where applicable.)

*3.1.1.3(b)(ii) European studies*

In a Finnish study by Kontsas et al (1998), levels of PCBs in exposed and non-exposed workers from 3 sawmills were analysed. In this study all participants were males, aged 31-52 years. The total sample size for the unexposed group was 18 and the mean plasma level for PCB #126 was 69.4 pg/g lipid. The mean plasma value for PCB #169 at 3 different sawmills was 82.8 pg/g lipid. The mean I-TEQs for PCBs for non-exposed workers was 11.1 pg/g lipid and ranged from 8.3 to 14 pg/g lipid for 3 sawmills. The mean WHO-TEQs for PCB #126 and PCB #169 for the Australian study were 1.42 and 0.16 pg/g lipid, respectively for males aged 31-60 years.

A study in Madrid, Spain, by Jimenez et al (1996) evaluated the background serum levels of non-*ortho* PCBs in 11 unexposed people during 1993. The age of the donors

ranged between 19-55 years and the mean level found for non-*ortho* PCBs was 85.47 pg/g lipid. Calculated I-TEQ values were 7.03 pg I-TEQ/g lipid for non-*ortho* PCBs (PCB #126 plus PCB #169). In comparison, the mean WHO-TEQ for non-*ortho* PCBs (PCB #126 plus PCB #169) for the Australian population was 1.98 pg/g lipid.

Covaci et al (2001) analysed concentrations of PCBs in 47 pooled human serum samples from 200 women between 50-65 years living in two areas of Flanders, Belgium in 1999. The women sampled were not at risk from occupational exposure to PCBs or dioxins and resided in either a rural or a suburban area of Antwerp. The mean WHO-TEQ value for PCBs was 25.8 pg/g fat and ranged from 20.3-32.4 pg/g. The mean total PCB WHO-TEQ (sum of 12 congeners) for Australian women aged > 46 years (averaged across 46-60 and >60 years age groups; see Table 3-2) was 6.4 pg WHO-TEQ/g lipid, which is substantially less than the level in Belgian women.

Johansen et al (1996) determined the concentrations of 19 PCB congeners in whole blood samples from 24 consumers of crabs and 10 referents in a contaminated fjord area in Norway. The subjects included in this study were all males aged between 40-54 years. The TEQ for PCBs was approximately 45 pg WHO-TEQ/g fat compared to 3.7 pg WHO-TEQ/g lipid for Australian males aged 31-60 years.

In Germany, Päpke et al (1996) analysed 104 blood samples in 1994 for PCB #77, #126 and #169 where the mean age of the participants was 38.5 years. The mean blood concentrations for the 3 congeners were 16.1 pg/g, 80.3 pg/g and 101.8 pg/g lipid, respectively. The authors did not provide TEQ values and also reported that the levels of PCB #77 may be affected by an outside contamination. For Australians aged between 31 to 45 years, the mean serum concentrations of PCB #126, PCB#169 and PCB #77 were 14.0, 10.5 and 25.9 pg/g lipid, respectively.

In another German study, Wuthe et al (1996) measured the blood fat concentrations of PCBs in pooled samples from children and individual samples from adults. The sample of children consisted of 142 boys and 144 girls aged <12 years. For the 15 adults, the mean blood values of PCB #126 and PCB #169 were 67.3 and 116.2 ng/g lipid, respectively. The children were from 3 different areas in Southern Germany, an urban industrial area, an industrial area within a rural setting, and a rural area. The mean sum value of PCB #126 for the 3 regions were, 44.8 ng/g, 45.2 ng/g and 41.9 ng/g lipid, respectively. For PCB #169, the levels were 29.4 ng/g, 30.3 ng/g and 34.0 ng/g lipid. The authors did not calculate TEQ values. In comparison, Australians aged <16 years exhibited PCB #126 and #169 serum levels of 13.1 and 5.3 pg/g lipid, respectively, while Australians aged 19-60 years had PCB #126 and #169 serum levels of 14.9 and 11.2 pg/g lipid, respectively.

*3.1.1.3(b)(iii) Asian studies*

In a study of 50 “normal” Japanese women aged ca. 20 years and without children, Iida et al (1999) reported a mean WHO-TEQ for coplanar PCBs was 4.9 pg/g lipid for samples collected between 1993-1994. In this current study, Australian females aged 16-30 years had a mean total PCB TEQ of 2.4 pg WHO-TEQ/g lipid. In the Japanese study, levels of PCB126 and PCB169 were 46 and 23 pg/g lipid respectively a mean

non-*ortho*-PCB concentration (ie. PCB 77, PCB81, PCB126 and PCB169) of 15 pg/g lipid in the Australian study.

A study of 253 Japanese subjects (112 women and 131 men), conducted by the Environment Agency of Japan in fiscal year 1998 (Ueda, 1999), reported a mean WHO-TEQ for coplanar PCBs of 7.3 pg TEQ/g fat with a range of 0.33-32 pg/g fat. There were no significant differences in PCB levels detected between 234 subjects who resided in "normal environmental regions" and 19 who resided in the vicinity of waste incineration facilities. In the Australian study, individuals aged between 16-60 years had a coplanar PCB serum concentration of approximately 26.5 pg/g lipid and a mean WHO-TEQ of 1.7 pg/g lipid (averaged across 16-30, 31-45 and 45-60 year age groups; see Table 3-2).

### *3.1.1.3(b)(iv) New Zealand studies*

Buckland et al (2001) analysed 1,834 samples for levels of PCBs. Samples were obtained from people of both sexes, aged >15 years, Maori and non-Maori. The samples were pooled according to age, ethnicity, sex and geographic location to give 60 pools. The weighted mean levels of PCB #126 and PCB #169 were 30 and 20 pg/g lipid respectively. The total PCB TEQ (including ½ LODs) was 6.86 pg WHO-TEQ/g lipid.

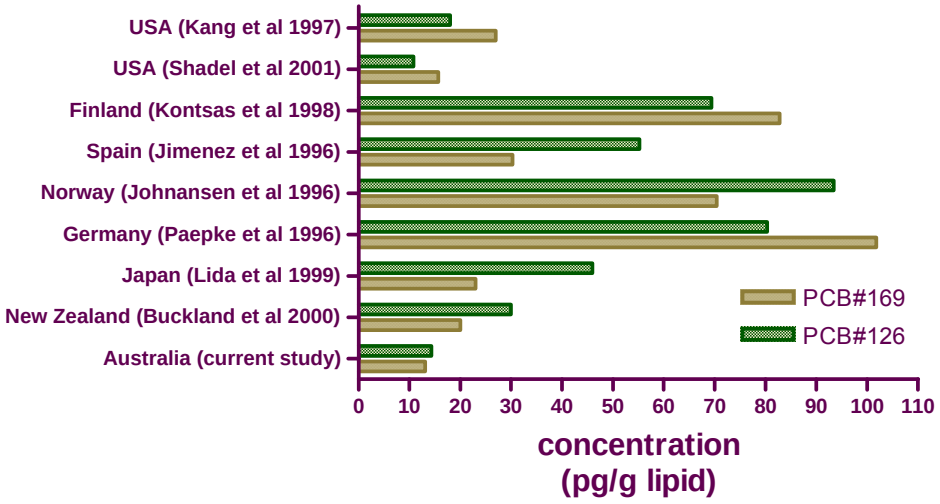

**Figure 3-6 International comparison of blood serum levels of PCB #169 and #126 in non-occupationally exposed populations (pg/g lipid).**

Data are reported on a lipid weight basis.

### *3.1.1.4 Derivations of body burden of PCDD/Fs and PCBs*

For appraising the health risks of PCDD/Fs and PCBs to Australians, it is useful to also consider the concentrations of PCDD/Fs and PCB normalised for body weight and percent body fat (body burden). Estimation of the total body burden takes advantage of the fact that highly lipophilic, bioaccumulative compounds are relatively evenly

distributed in all lipid in the body. Measuring the dioxin concentrations in the lipid content of blood provides an estimation of dioxin concentration in all fat stores in the body. Data on the percentage of total body weight which is fat can then be used to estimate total body burdens.

### *3.1.1.4a Body Mass Index and Percent Body Fat*

For the derivation of body burdens, an average percent total body fat for each region and age group was required. Ideally percent total body fat is measured using a variety of methods such as skin fold measurements or bioimpedance readings. Unfortunately for the Australian population, empirical percent total body fat data corresponding to the stratification criteria used in the dioxin serum level study was not available. Consequently percent total body fat for the Australian population was derived from the body mass index (BMI[25]) data, as this data was available for the different age and regions employed in this study. The Australian Bureau of Statistics provided mean BMI data collected using two different surveys. The 2001 National Health Survey (NHS, 2001) provided BMI data for individuals aged >16 years and the National Nutrition Survey conducted in 1995 (NNS, 1995) provided BMI data for individuals <16 years. The geographical stratification between the 2 different surveys was similar, but not identical (Table 3-3, Appendix V). However given the small differences in the mean BMI data between regions (Table 3-3), the differences in geographical stratification between the two national surveys were inconsequential.

### *3.1.1.4(b) Model derivation and verification*

[25] Body Mass Index (BMI, kg/m$^2$) is defined as the percent body weight per body area and is calculated by dividing body weight (kg) by the square of body height (m$^2$).

The derivation of percent body fat content from BMI data was performed using a modified literature model initially designed for white Americans (Equation 1) (Gallagher et al, 2000). The modified model was developed and verified using a limited data set containing percent body fat and BMI for the Australian population provided by the International Diabetes Institute (IDI) (Jonathan Shaw, Personal communication, 2004). This limited data set measured percent body fat by bioimpedance and calculated the BMI by standard methods. The data were stratified by age (25-34, 35-44, 45-54, 55-64 and 65-74 years) and sex, but not by regions. The equations used to derive percent body fat (%BF) from the BMI data for Australian males (Equation 2) and females (Equation 3) were as follows:

*Equation 1:* White Americans (Gallagher et al, 2000)

$$\%BF = 64.5 - 848 \times (1/BMI) + 0.079 \times AGE - 16.4 \times SEX + 0.05 \times AGE \times SEX + 39.0 \times SEX \times (1/BMI)$$

*Where SEX = 1 for males and 0 for females*

*Equation 2:* Australian Male [Sex = 1]

$$\%BF = 74.5 - 848 \times (1/BMI) + 0.079 \times Age + 0.05 \times Age + 39.0 \times (1/BMI) - 0.131 \times Age$$

*Equation 3:* Australian Female [Sex = 0]

$$\%BF = 64.5 - 848 \times (1/BMI) + 0.079 \times Age + 0.048 \times Age$$

Without modification and using the IDI data, equation 1 gave %BF values that were up to 5% lower than the actual %BF measured by bioimpedance. (Average standard error of estimate [SEE] values were 1.79% for males and 2.79% for females.) The limited data set illustrated that the %BF of Australians increased with increasing age to a greater extent than that predicted by the model of Gallagher et al (2000), hence the model was modified to accommodate the greater dependence of %BF on age. The derived %BF values using the modified algorithms and BMI data provided by the IDI are shown in Table 3-4. The derived %BF values had $R^2$ and average SEE values of 0.53 and 0.33% [males], and 0.51 and 1.39% [females].

**Table 3-4 Verification of algorithm to derive %BF from BMI data for a limited data set**

| Age (years) | Male | | | | Female | | | |
|---|---|---|---|---|---|---|---|---|
| | BMI[#] | %BF[#] | Calc. %BF[$] | SEE* (%) | BMI[#] | %BF[#] | Calc. %BF[$] | SEE* (%) |

[#] IDI data (%BF calculated from bioimpedance measurements, BMI calculated by standard methods).

$ Derived %BF using equations 2 or 3.

These algorithms were then used to derive %BF values from the BMI data supplied by ABS for the 5 regions and 5 age groups. These derived %BF values are reported in Tables 3-6 – 3-10 in the following section, and in appendices VII and VIII.

*3.1.1.4(c) Dioxin body burdens using derived %BF values*

The maximum and mean body burden of total dioxins expressed as ng WHO-TEQ/kg bw for both genders and the 5 age groups averaged across the 5 regions are listed in Table 3-5.

**Table 3-5 Serum concentrations and body burden of total dioxin (PCDD/Fs plus PCBs) WHO-TEQ in Australians by gender, and age group, averaged across all regions.**

| Sex | Age (years) | Serum concentration (ng WHO-TEQ/kg lipid)#* | | Body burden (ng WHO-TEQ/kg bw) | |
|---|---|---|---|---|---|
| | | Maximum | Mean | Maximum | Mean |
| Male | <16 | 8.60 | 6.32 | 0.61 | 0.53 |
| | 16-30 | 7.50 | 5.69 | 1.41 | 1.21 |
| | 31-45 | 10.50 | 8.02 | 2.18 | 1.92 |
| | 46-60 | 14.80 | 12.44 | 3.30 | 3.05 |
| | >60 | 21.60 | 18.51 | 4.68 | 4.35 |
| Female | <16 | 8.30 | 6.05 | 2.14 | 1.72 |
| | 16-30 | 8.10 | 6.06 | 2.30 | 1.86 |
| | 31-45 | 13.50 | 8.88 | 4.30 | 3.11 |
| | 46-60 | 15.60 | 12.09 | 5.79 | 4.71 |
| | >60 | 28.00 | 21.39 | 11.34 | 9.61 |

# TEQs calculated using the 1997 WHO TEFs. Data reported includes LODs for non-detected congeners (i.e. upper bound TEQ).

* Maximas and means were calculated using data from individual pools.

Body burdens for PCDD/Fs, PCBs and total dioxins (PCDD/Fs plus PCBs), for males and females for each age group and region are presented in Tables 3-6 – 3-10 in the following section.

*3.1.1.6(c)(i) Effects of gender on the body burden of PCDD/Fs and PCBs*

The body burden data (Table 3-5) show a strong gender difference, with, on average a 54% (range 34-110%) higher body burden in females compared to males for the same age group (Figure 3-7). Generally, serum concentrations were similar for males and females within the same age group, except for the older age group, where women appeared to have higher concentrations. However, when normalised for body weight, women exhibited higher total dioxin body burdens across all age groups (Figure 3-7). This appears to be primarily influenced by the higher body fat content in women compared to that of men. As shown in Tables 3-6 – 3-10, body fat was on average 40% higher in women compared to men for the same age group.

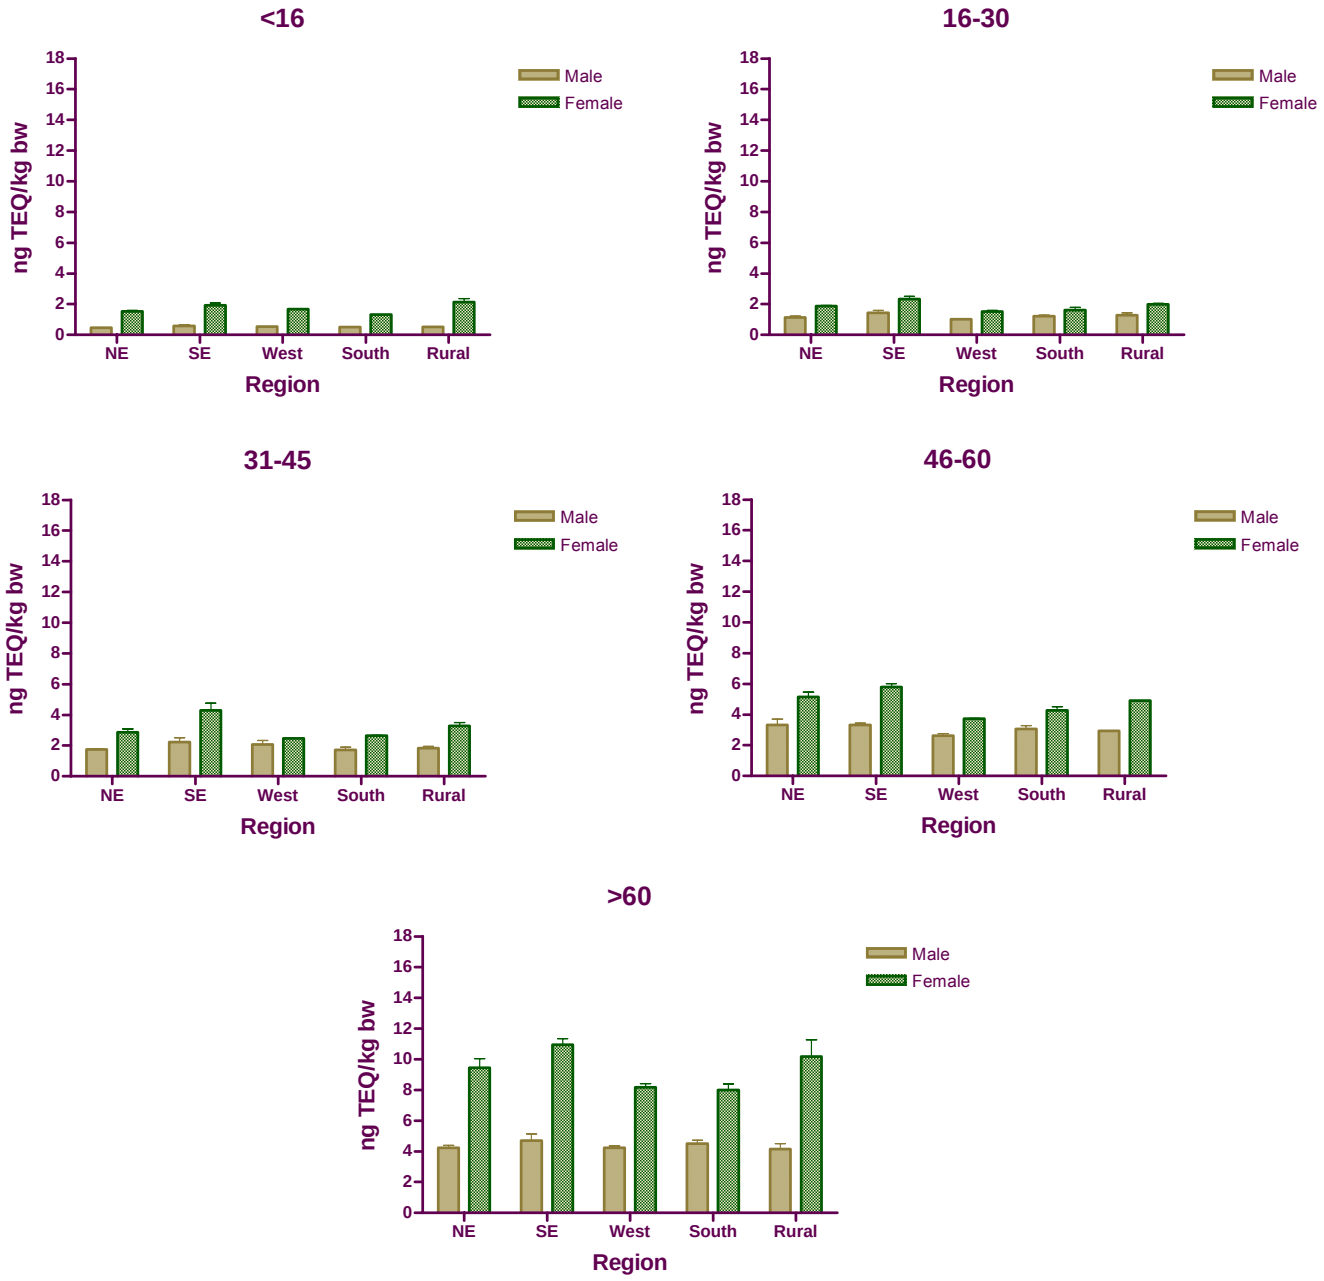

**Figure 3-7 Mean body burden of total dioxins (WHO-TEQ/kg bw) in a representative group of the Australian population, by sex, age group and region.**

Data shown represent mean body burdens for males and females from the all regions over the five age groups. Regions are Southeast urban (SE), Northeast urban (NE), South urban, West urban and rural.

*3.1.1.4(c)(ii) Effects of age on the body burden of PCDD/Fs and PCBs*

The trend of increasing total WHO-TEQ (PCDD/Fs plus PCBs) serum concentrations with age across all regions was also noted for total dioxin body burden (Figure 3-8). In males and females, there was a 6 to 8-fold increase in the total dioxin body burden of individuals aged >60 years when compared with the younger strata. Females >60 years had the highest mean dioxin body burden of 9.80 ng WHO-TEQ/kg bw compared to men of similar age (4.35 ng WHO-TEQ/kg bw) (Figure 3-8). Note that this difference in body burden (ie. amount per kg body weight) is a reflection of the significantly increased amount of body fat per unit bodyweight in females than in males (see %BF values in Tables 3-6 to 3-10); mean levels per unit lipid were similar for males and females.

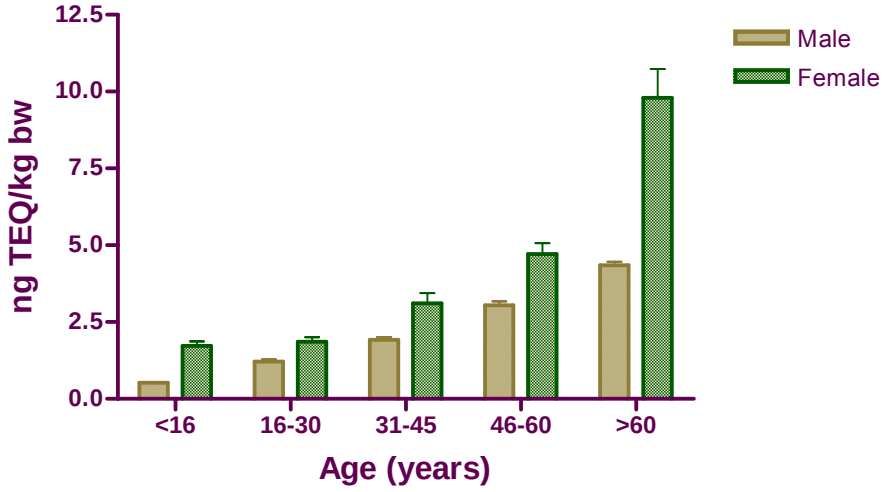

**Figure 3-8 Mean body burden of total dioxins (WHO-TEQ/kg bw) in a representative group of the Australian population by sex and age group.**

Data shown represent body burdens for males and females from the 5 age groups averaged across 5 regions.

*3.1.1.4(c)(iii) Effects of region on the body burden of PCDD/Fs and PCBs*

The individual body burden profiles of the Australian population for the 5 regions are shown in Appendix VI. Small geographical variations were observed, with total dioxin (PCDD/Fs plus PCBs) body burden tending to be marginally higher in the Southeast region (Sydney, Canberra, Wollongong, Newcastle and other major population centres in NSW) compared to other regions. This finding is unlikely to reflect an actual difference in exposure of the population in this region. With the exception of rural females, aged >60 years, there were no differences in body burden values between the urban or rural regions for either sex. For older women (>60 years; 10.2 ng WHO-TEQ/kg bw) residing in the rural region, body burden values were approximately 10% higher than similar aged urban females (9.1 ng WHO-TEQ/kg bw).

#### *3.1.1.5 Derivation of the average lifetime daily exposure (ALDE)*

Assuming steady-state conditions, the following expression can be used to estimate an approximate human daily intake to achieve the calculated body burden.

*Intake (ng/kg bw/day) = body burden (ng/kg bw) x (0.693/half-life)/f*

Where f is the fraction of the intake dose that is absorbed. Half-life is the average half-life of dioxins in the human body, assumed to be 7.5 years.

Dioxin compounds are absorbed through the gastrointestinal tract, skin and lungs. The degree of absorption varies with each congener, the route of absorption and the vehicle in which the dioxin is ingested. For the general population, oral intake of trace levels of these contaminants in foods accounts for 90% or more of the total intake. Findings in experimental animals indicate that oral exposure to TCDD in the diet or in an oil vehicle results in absorption of >50%, and often closer to 90% of the administered dose. More soluble congeners are almost completely absorbed, whilst extremely insoluble congeners, such as octachlorodibenzo-p-dioxin (OCDD) are poorly absorbed. Limited data from a single human volunteer suggest a high level (>85%) of absorption of TCDD in corn oil from the gastrointestinal tract. Thus, in the following calculations, the fraction of the dose that is absorbed was assumed to be 90% or f = 0.9. This value is in agreement with that used to model the ALDE for the New Zealand population, but is higher than the 50% value used by the WHO.

The WHO, in its 1998 re-evaluation of the tolerable daily intake, used a half-life of 7.5 years to estimate human intakes from animal body burden data (Van Leeuwen et al, 2000; Van Leeuwen & Younes, 2000). In the current risk appraisal, the half-life value used by WHO of 7.5 years has been used to calculate average lifetime daily intakes of dioxin compounds from body burden estimates[26].

The estimates of the equivalent daily intake of dioxin compounds for Australians by region, age and sex are reported in Tables 3-6 to 3-10.

It should be noted that the ALDE estimates in Tables 3-6 to 3-10 are calculated according to a simple steady-state model. As stated above, the calculations assume a half-life of 7.5 years for all dioxin-like compounds, assume that this half-life is constant over a person's lifetime, and assume a constant fraction absorbed. None of these assumptions are likely to be correct. For example, the average half-life probably increases with age (see 3.2.3 and discussion at 3.7.2). There is no perfect way to present these calculations, given all the uncertainties and the desire to use a simple rather than a very complex model. Therefore, these calculated figures are approximate estimates of dioxin intake at different ages and it should be borne in mind that significantly different values could be calculated using somewhat different assumptions for the half-life or the fraction absorbed for the different age groups.

[26] A recent analysis indicated mean half-lives of 6.9 years for the slower elimination period (measured from 3 to 16.35 years after exposure) in Seveso adults and 6.9 years for the slower elimination period for Ranch Hand veterans (9 to 33 years after exposure) (Michalek et al, 2002); both groups had an initial more rapid elimination phase, consistent with a two-compartment open model.

The ALDE estimates for total dioxins (PCDD/Fs plus PCBs) are similar to those reported for New Zealand (Buckland et al, 2001), with a minimum value of 0.13 pg WHO-TEQ/kg bw/d for males <16 years in the northeast urban region of Australia to a maximum of 2.96 pg WHO-TEQ/kg bw/d for women >60 years in the southeast urban region. The mean ALDE for all data was estimated as 1.32 pg WHO-TEQ/kg bw/d. (The mean ALDE estimated from New Zealand data for ages 15-65+ was 1.4 pg WHO-TEQ/kg/bw/d).

**Table 3-6 Serum concentration, body burden and ALDE for PCDD/Fs, PCBs and total dioxins (PCDD/Fs plus PCBs) for Australians by gender and age for the Northeast urban region.**

| Sex | Dioxin | Age (years) | Mean [serum][1] (ng WHO-TEQ/kg lipid wt) | %BF[2] | Body burden (ng WHO-TEQ/kg bw) | ALDE[3] (pg TEQ/kg bw/d) |

where the half-life is taken as 7.5 years and f, the fraction of dose that is absorbed, is assumed to be 0.9.

### *3.1.1.8 Conclusions*

Whilst the serum study is an important assessment of the levels of dioxin compounds in the Australian population, it has a number of limitations. In particular, by pooling samples, it is not possible to examine the distribution of contaminant levels among individuals. Additionally, because of the use of de-identified samples there was no means by which the length of residence in a particular area could be verified. Nevertheless, the study has enabled a number of important conclusions to be made.

1. **National averages:** the National average serum concentration and body burden for dioxin compounds was 10.9 ng WHO-TEQ/kg lipid and 3.22 ng WHO-TEQ/kg bw, respectively. The mean ALDE for all data was estimated as 1.32 pg WHO-TEQ/kg bw/day.

2. **Age variations:** Serum concentrations of PCDD/Fs and PCBs were found to increase with age. Thus, the mean serum concentration of PCDD/Fs ranged from 3.54 ng WHO-TEQ/kg lipid for <16 year old females, to 14.30 ng WHO-TEQ/kg lipid for the >60 year old females. For PCBs, the mean serum concentration ranged from 2.11 ng WHO-TEQ/kg lipid for <16 year old males, to 9.99 ng WHO-TEQ/kg lipid for the >60 year old females. For total dioxin compounds (PCDD/Fs plus PCBs), the mean serum concentration ranged from 6.05 ng WHO-TEQ/kg lipid for <16 year old males, to 24.26 ng WHO-TEQ/kg lipid for the >60 year old females. As noted elsewhere, older people are likely to have experienced higher exposures due to higher environmental levels of dioxin-like compounds in the mid-20$^{th}$ Century; since then, environmental levels have been decreasing (see further discussion on this below).

Similarly when normalised to body weight, serum concentrations increased with age. Thus the mean body burdens for total dioxins (PCDD/Fs plus PCBs) ranged from 0.47 ng WHO-TEQ/kg bw for <16 year old males to 4.70 ng WHO-TEQ/kg bw for >60 year old males, and from 2.14 ng WHO-TEQ/kg bw for <16 year old females to 11.34 ng WHO-TEQ/kg bw for >60 year old females. The higher body burden in older people is likely to reflect higher historical environmental exposures to dioxin compounds in the 1960s and 70s, and the fact that these compounds are only slowly metabolised and excreted from the body. Additionally, given that older people have higher percent total body fat compared to the younger strata, the higher body burden also results from the continuous deposition of dioxin compounds in adipose tissue.

3. **Geographical variations:** Small geographical variations were observed, with total dioxin (PCDD/Fs plus PCBs) serum concentrations and body burdens tending to be marginally higher in the Southeast region (Sydney, Canberra, Wollongong, Newcastle and other major population centres in New South Wales) compared to other 3 urban (South, West and Northeast) and rural regions, with the exception of older rural women (>60 years). For older women (>60 years; 10.2 ng WHO-TEQ/kg bw) residing in the rural region, body burden values were approximately 10% higher than similar aged urban females (9.1 ng WHO-TEQ/kg bw). These findings are unlikely to reflect any actual differences in exposure of the population in these regions.

4. **Sex variations:** Generally no clear differences in serum concentrations were found between males and females, although women from the oldest age group (>60 years) appear to have higher concentrations then similar aged men. However when expressed as body burdens, women consistently had higher amounts of dioxin compounds per kilogram body weight than men for the same age group. This was probably largely due to the higher total body fat in females compared to males. It could reasonably be expected that breast-feeding might help reduce serum levels of dioxins; however this study which used pooling of a limited

number of pathology samples across a range of age groups would not be likely to detect such an effect.

The study also found that, on average, PCBs accounted for approximately 30-40% of the total TEQ associated with the general population exposures to dioxin compounds.

5. **International comparisons:** In the Australian population, the blood serum levels of PCDD/Fs expressed as WHO-TEQ pg/g lipid were generally lower than those observed in American, European or New Zealand studies, and similar to values reported in Asian studies.

For the majority of studies, the concentrations of PCB #169 and PCB #126 in blood sera from the Australian population was lower than that reported for subjects from America, Europe, Asia or New Zealand. Moreover, in some studies the level of PCB #126 or PCB #169 was up to 10-fold lower than that reported in some European countries (Norway, Germany or Finland).
